Unfortunately an outdoor resonant antenna for anything other than, oh,
11 meters, is out of the question for me. I'm in an apartment and
while there's a large fenced in backyard where I could put up a
stealth antenna, it's on the wrong side of the building from my apartment.

I have been going outside with a portable to listen in on 6900-6955
(mostly 6925). It works well enough once I get away from the overhead
power lines, etc. But the chilly breeze is aggravating a respiratory
infection I'm trying to get over.

Looks like I'm back to considering a reasonably well designed (and
priced) loop.

Yup, I recall you mentioning that before. The PK loops are reasonably priced. Might be worthwhile to have one designed just for a particular meter band and stick with a random wire for everything else.

Heck, I get good enough reception of the major SW broadcasters with little more than a paper clip stuck into the Hi-Z input! So nothing fancy is necessary for listening to Radio Netherlands, CRI, Taiwan, Japan, any of the relays via Sackville or the propagation propaganda pros from Radio Havana Cuba (heck, it's worth listening to 'em dis the U.S. just for the music and Arnie Coro).

Why not try a skirting board loop antenna?

In your largest room, run one or more turns of multi-stranded, insulated, copper wire (speaker cable should be OK) around the outside of the room up against the skirting board. Or one or more turns around the outside of the room under the carpet. Because a loop's capture ability is a function of its area, you get the maximum indoors catch area, in the warm, in an inconspicuous fashion. A 4 foot loop resonant at about 4 MHz will have a gain in the region of about -15 dB. A skirting board loop resonant at the same frequency can have a gain approaching 4 dB. Don't take my figures for gospel but there is a large difference. If any of the technophiles on the forum want to post the definitive comparison, I welcome them (I'd like to know but am too lazy to run the experiments).

The number of turns depends on the perimeter of your room relative to your frequency of interest plus a number of other factors such as the method of construction - eg is there iron mesh in the concrete floor?, position of electrical wiring, plumbing etc. A single turn loop in a room 24 feet by 20 feet in a wooden building should resonate somewhere around 8-9Mhz (This is a guess - anyone confirm or deny?). It is harder to get that perfect length than using a multiple turns on a small area loop because each turn is just so long but the performance benefits are worth the struggle.
Anyway you should aim for your loop to to be slightly shorter than the resonant length so you can tune it down to your desired frequency with a variable capacitor. Just connect the variable capacitor to the ends of the loop wire. If your length is right you will hear an increase in signal as you adjust the capacitor to resonate the loop at your frequency of interest. If the loop resonates above the FOI, lengthen it----resonates below, shorten it. You can, of course, use the loop untuned by running just one turn and leaving the capacitor out but the advantages of the tuned loop will be unavailable - just put in a loop with the largest area. There is no way to predict the actual performance of a skirting board loop because of the wide variability in the construction and location of rooms and so some experimentation is needed.

Inside the building you expose your antenna to more electrical interference. Self-adhesive aluminium foil tape under and on top of the loop will go a long way to provide some electrostatic rejection. This is because the aluminium is highly conductive to electricity but has poor magnetic abilities which allows the magnetic part of the radio signal to get to the magnetically sensitive loop. Don't make the tape continuous around the whole loop as it will become a shorted turn and suck all your signals away - leave a gap of a few inches (at the tuning capacitor is good).
The tape will alter the resonant frequency of the loop - experiment.

Now you've got to couple the loop to the radio. If your loop is tuned don't connect the ends of the loop directly to the radio because a tuned loop is a high impedance device. The input to most radios is a low impedance and this low impedance will load up the tuned loop and severely impair its performance. Wind a few turns of thin, insulated wire on a ferrite rod and connect the ends to a suitable plug using coax cable. Lay the rod across the loop.
If your loop is untuned, connect the ends to the coax or use a balun between the loop and the coax. I don't know what ratio balun to recommend because of the variability in room sizes and FOI but a 4:1 is a good place to start.

Before committing to lifting your carpet or other serious activities, just place the wire near as near as possible to its final position and do your experiments/adjustments. Once you've maximised its performance, put it into its final position, the performance won't change much.

Cost: speaker cable 40c/metre; ferrite rod <$5; plug $1.50; coax $1.10/metre; aluminium tape - don't know - never bothered; coupler wire (free - pull an old transformer apart).

I think my copy of Carr's "Receiving Antenna Handbook" has a very
similar scheme.

I've been trying to avoid using a tuner, for the sake of ease in
bandscanning, but I'm not sure that's practical. What I might end up
doing is attaching a random wire and tuned loop to the receiver via a
switchbox. Use the random wire just to check for signals in the clear
and switch to the tuned/tunable loop to improve reception, reduce
noise, etc.

As a photographer I've accumulated way too many tripods. I'll
probably dedicated one of 'em to a loop stand. The nearly infinitely
adjustable angles should make it handy for reorienting a loop to
minimize local noise.

4632. Space-Challanged Lot...

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-01-01 14:46:14 UTC
From: Donald Saunders
Topic: 4632 Message: 4632

Hi All,

I'm in a unique predicament. My double city lot is only
60' wide, but 275' long. There are electrical high lines
at the back of the lot and the service line comes from a
pole on the back, Northeast corner along the East side of
the lot about 100 feet to a "pick-up" pole (Electric Co's
definition), then crosses over the yard to the Southwest
and attatches to the back, middle of the house.

Not wanting to put up a wire antenna over an electical drop,
I'm some what handi-capped, both physically by space and
body (severe arthritis). Do any of you have plans for a
rectangular full-wave loop that I could run (on the West
side of the house, say 25' wide and 200'long on the side?

I'll feed it with 450 ohm ladder line and use an MFJ 949-E
tuner to match the Icom 706 Mark II-G.

Thanks in advance,

Respectfully submitted,
73,
"Happy New Year!"

From: Hue Miller
Topic: 4633 Message: 4633

The Altoids tin would just be a box for the amplifier.
Then, in my imaginings, there would be a loop of
flexible spring wire coming out of it, off the narrow
end of the tin, so the amplifier proper can fit in a
jacket pocket. It occurred to me that i would want
to somehow retain VHF performance with this
antenna, whether tuned or untuned loop - i don't
think that's the most difficult part, however.

I saw in a recent "Radcom" some things offered for
add-ons for scanners but the vulnerability of some
add-on box that attaches to the antenna connector
on top the scanner looks scarey. I mean it does not
look convincing as to mechanical robustness, as well
as it's tuned by a knob to a single frequency, and i'm
more interested in wideband reception for a pocket
scanner.

Re picking up the hobby broadcasters on 40 meters:
will a portable with a whip antenna really do this?
Reception out here on the Oregon coast must be much
worse than there. Late night, it's amazing how empty the
SWBC bands are.

Re foxhole radios in Pacific War: very interesting and VERY
surprising to me. I would not thought a razor-blade radio
could pick up Japan HF broadcasts, as these radios were
just not as sensitive as a crystal radio with a more
conventional detector, and i've never known that aircrew
headphones were either reknown for sensitivity and i think
they were based at 600 ohms, is this not right. Plus, Japan
was broadcasting with power of (i think i read) 40 kw on its
shortwave transmitters. Still, this may have been possible;
It's an overwater route and in the hundreds of miles only.
Maybe that interesting anecdote will even inspire me to try
it out. If you had said, used razor blade radio to listen to the
local Armed Forces Radio, i could easily accept that; most
every island with a military population in the thousands, after
being pacified, got a AFRS radio station of 1 kw power, and
some smaller islands without an AFRS station had local-built
stations of lower power. But - i had NEVER heard or read
about the Pacific War connection to the foxhole radio - that
REALLY deserves to be more widely known. It occurred to
me that it must have been a bit difficult to set up these
foxhole radios to work - you had to have Japan on the air -
plus the fading normal to shortwave radio "may" have meant

trying to find a hot spot on the blade, a frustrating experience.
-Hue Miller

OK, that's enough. Len, you keep straying into insults and bullying.
I've warned you before.

You could have simply said what I've left of your message below, and
changed the subject line since nothing in your post had anything to do
with foxhole radios or loop antennas:

--- In loopantennas@yahoogroups.com, Len Warner <novost@...> wrote:
snip
> And, after all those pious words, you yourself CBA to trim...
snip
> From Yahoo! Groups Help: ... trim all the irrelevant quoted text
> out of your message (as a courtesy to the other members of
> the group to make the digest easier to read).

-MY- thoughts on the subject:
Trim down to only what is needed to understand the reply.
Trim down to only what is needed to understand the reply.
Trim down to only what is needed to understand the reply.
Top, bottom, interleave posting, I don't care. Use proper quoting and
text only and it doesn't really matter. We've discussed this enough.

The facts: this isn't the old Fidonet. Back then, people bottom posted
because you also included much of the previous discussion as someone
might read your message weeks later and downloading old messages was
slow and difficult. Deleting selected portions was not that easy, it
meant manually moving your pointer with the arrow keys and hitting the
backspace over and over. It was socially acceptable then to bully
people right out for failing to bottom post. That is -not- acceptable
behavior here.

It isn't Fidonet any more. Even Usenet is different. Looking up the
old messages is much easier, and most of us get online to check email
at least every few days, so discussions are much easier to follow. As
a side effect, it's much easier to read a top-posted reply than bottom
posted. Sadly, this also means people tend not to notice just how much
old message is attached and trimming, although -much- simpler with a
mouse, gets forgotten. I consider it sufficient to send a reminder now
and then. No sense using a bazooka to kill a few mosquitoes, that's
how more than one list has destroyed itself.

If you wish to discuss this more, contact me -off- list. If necessary,
I'll start a separate list to discuss posting rules or lack thereof,
but NOT ON THIS LIST.

From: Chris Trask
Topic: 4637 Message: 4637

Over the holidays, I took a great deal of time to investigate some ideas that I had with regard to the design of lossless feedback amplifiers in an effort to improve the dynamic range of active antennas, both in terms of noise figure (NF) and distortion (IMD products). I had quite a bit of success, and wrote a monologue about some of what I did:

http://www.home.earthlink.net/~christrask/Lossless%20Feedback%20Amplifiers.pdf

The details of all this, plus some other advanced techniques, are part of a full article that I'm presently writing.

Don,

I'm trying to visualize your situation from the description. Would you be able to put up a narrow(ish) delta shape with the pointy end toward one corner of the house without being too close or crossing the power drop? You certainly have the room for a full wave 80 meter delta there if you can avoid the powerlines. Failing that, maybe a bobtail curtain or something? Not sure where your pattern would end up pointing with that though. With a corner fed delta, a big lobe comes off the feed point and opposite. Mine works FB.

Hello there
I am going to build the Antenna that is in this article.
I have a few Question on this parp.
If your receiver has an external antenna jack use a short length of coaxial cable to connect
from the jack to the antenna. For the horizontal doublet connect the shield to one leg of the
antenna and the center conductor to the other leg. For the vertical doublet connect the shield
to the center of the antenna and the center conductor to a point about 6" to 12" higher. Hose
clamps are ideal for this and permit moving the center conductor feed point up or down to
find the best spot. The same technique is used for the loop. Connect the shield to the center
of the bottom member and the center conductor some 6" to 12" away

I really don't understand this
JIM F.

Jim,

I have only a very vague recollection of that article but, as JR points out, the description of the feed method for the vertical doublet and the loop is that of a simple gamma match. The coax shield is connected to the zero-voltage point at the center of the doublet or loop. The coax center connector is connected to a point offset from center that experimentally provides a match to the cable (usually 50 Ohms).

Richard ,
I put wire around the deck on the E,W,N sides
it also runs in the house 30'(north) the 3' East then back to South
to the radio.I had about 20' left over, I was tuning the radio found station
but it was not to clear so I drop the 20' on the floor and the radio was so clear and loud.
so I left well enough along. At 9 AM CST. today I pick up China International
at 13739.

Sounds like that is an improvement. I cannot, however, trace
the course of this wire in my mind's eye... I guess it doubles
back on itself 30 feet? Typically, they do not work so well if
they double back against themselves. But, then again, sometimes
they just defy all logic and work well in spite of any theory!

Can you draw out the pattern somehow?

But good to hear you are making progress !!

ok I went the 10' along the wall on the deck
then went 12' along the length of the deck
then went 10' on the other side of deck.(outside)
In side -the wire comes in the condo thru the same hole that the Satellite dish
uses. then went across the floor joyices 30' to other side of basement.
then 3' I made a left turn towards (in) the basement.
then back 8' towards the radio. remember the deck is 5-6' higher than the basement.
I guess out side it looks like a horse shoe(3 sided)
None of the wire crosses or touch.

The funky thing about voodoo antenna rigging is that they usually work very well within at least one narrow frequency range.

I'm continually tweaking my crude indoor antennas and find that I can usually optimize performance for a certain meter band, but at the expense of broadband performance. Sometimes it's just a matter of rerouting a leg of a misshapen random wire to improve reception on one band, then tweaking it again for another meter band.

Whoa -- Yes... I think I get it now..., you must be located
on the other side of the house away from the window
that is near the deck! That's quite a run. I thought you were
sitting inside that window on the same side of the house as
the deck is.

But... I take it the good news is that your reception is better!
Yes?

Bruce,

Thanks for the reply. I might be able to put up wooden mast
at the end corner of the house (about 20' from the west
property line and run it the length of the house (about 50'),
then continue it into the back yard to about 30 feet from the
high power (77kV) lines then East for 30', then back towards
the house and over the house. About mid-point of the back
yard, I'm going to have a vertically wound antenna (takes to
long to explain) so the wire could attatch to the antenna
support and then to the house.

Thanks,

Don/KA5-LQJ

Heh. You just described my Magnavox D2935. The membrane covered keypad makes it perfect for picnic DXing. I actually hafta wipe it off occasionally to remove the greasy pawprints. But that's why I love that radio. I wouldn't treat my Sony ICF-2010 or Palstar R30 that way.

I do get nitpicky about the way some folks slam down their antennas from the top instead of gently pulling 'em down from the bottom. I tried to fix my mom's Baygen antenna, which she'd half-broken at the top. She assumed it was fixed well enough to slam it down from the top and managed to completely break it this time. I'm not fixing it again.

I had a couple of DX-440s when they were made new. One of the jack sockets (headphone or external antenna?) was a bit fragile and broke when my ex- accidentally knocked it off a shelf. (I'm assuming it was an accident - she never did like my radio hobby.) I was disappointed by the relatively fragile construction, but it was easy enough to repair. Kinda wish I'd kept one of those radios but had too many and needed to thin out the herd.

I do have the circuit diagrams and a wiring diagram available as jpg's. Are you anyway interested? I could mail them to you.

The keypad consists of separate mechanical switches on a PCB, each covered by a plastic knob with a flat front face which lines up with a flat surface of the main housing. On this a flexible foil is placed with an adhesive to keep it in place.
This solution was chosen because we did not consider in 1982 the rubber keypads that are more or less the standard solution nowadays to be reliable enough for this rather expensive receiver.

Very interested! Would my e-mail or snail mail address be more convenient?

The D2935 continues to amaze me with its fine performance and excellent audio. I've considered buying another to see whether it's feasible to install a slightly narrower filter and to experiment with different external antennas.

Thanks,

Lex

Hi Don,

Is the issue here how to fit a loop onto your lot or do you also have
a qrn problem with the electrical line?

If the latter, some other considerations come into play beside the
solutions above.

4657. Re: Small Magnetic Loop Transmitting Antenna 10-30 MHz

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-01-09 14:30:16 UTC
From: capntripps2000
Topic: 4488 Message: 4657

I owned my AEA Isoloop 10-30 since 1993. Always attic mounted it faithfully performed beyond expectations even on 30M. This year the plastic housing broke rendering it useless.

I recently cut the antenna housing dumb-bell in two, salvaging the tuning capacitor assembly. Originally researching what it would take to modify the Isoloop for 40 meters I came upon Antennex and found much information on magnetic loops. I bought the 2 loop books on-line and using them as references built a 40/80M magnetic loop using the salvaged Isoloop tuning cap, 28 feet of 3/4" copper pipe, and some PVC. After a few nights spare time I had assembled a ground mounted 7' X 7' square loop. I laid down 8 ground radials 14ft long connected to each other but not the antenna (per recommendations of the Antennex loop books). I chose to use the gamma feed method rather than the Farday loop, since my goal was using the antenna on only 2 bands (gamma feed works for a 2:1 band spread while Farday loops are good for 5 bands). Getting the loop matched and tuned using an MFJ SWR analyzer was a breeze and I had the antenna on the air in one afternoon with excellent results. The AEA tuning cap range is approx. 36pf to 170pf. This made my loop tune 40M and 60M with an SWR < 1.5:1. I added a 7.5KV 150pf doorknob capacitor in parallel with the var cap and that brought the loop range down to 75/80M with SWR of 1.2:1 across the band. Adding the cap sacrificed 40M but the cap can be removed easily enough. 3:1 bandwidth is around 40Khz on 80M, not too bad. On the air tests were again impressive, in fact receiving was better on the loop as I was able to hear signals that were in the noise with my inverted L.

I will post a photo of the completed antenna in the photo section of this group.

The antenna is light enough to easily take into the garage for storage when not used during the day.

For anyone serious about building a magnetic transmitting loop antenna please review www.antennex.com and look into their two loop books. It made my work much easier and I am planning additional loops in the attic for the other bands.

A friend has just built a slightly different version of the WL1030
active loop. It works as well as the unit that I built that used
Litz wire inside a plastic tube.
See <http://www.ng-ronde.nl/wl1030/>

The page is in Dutch so it will help to use Babel Fish translation
at <http://world.altavista.com/babelfish>. The syntax gets a little
mangled but the idea is clear.

Look at the next to last image. Bill used a piece of flat 1" by 1/16"
aluminum bent into a circle fastened as shown in the photo.

I expected the antenna to be noisier then the original version, but
joy of joys it performs exactly as the original.

Bill used ugly or "dead bug" construction and encased the electronics
in clear aquarium silicon. The type with an alcohol solvent. Do
>>NOT<< use standard silicon sealant as it will corrode the electronics.
Another option is to a poly-urethane spray to protect the electronics.

The original construction plans at <www/wl1030.com> should be studied.

This is a good loop antenna. I still favor active dipoles but this
is an inexpensive alternative to the much vaunted ALA1530.

Terry

4661. Re: AEA Isoloop salvaged, converted to 40/80M transmitting loop

Topic: 4658 Message: 4661

Hi All,

I am consistently amazed by the small loop antennas. I have made a 4.25 foot diameter loop, using a butterfly cap from a long salvaged GR Vacumn tube bridge. Its indoors, about 15 feet up, and hears just fantastic. I have a squashed Faraday loop coupling. I oversized the loop, then squashed it down for best signals, and did a quicky VSWR check at low power, and it was right on. Do not TX here in the apartment, but SWL'g is quite fun too.

My best DX with it, is that presently in the morings I am reliably hearing the half a megawatt SW broadcast station on 9870 KHz from All India Radio (AIR Vividh Bharati) up to S7. With the DREAM software DSP (I have modified my Drake TR7 with a 12 KHz IF output), its quite listenable as most of the broadcast is music. Just amazing. I was never a serious SWL before, and never heard anything from that far away that reliably even so.

Dear,

I have such a PCB, I 've never built it.

Reason maybe: I built loopantennes myself, no amplification.

And since a year or so, there is the WAF: wife acceptance factor, or less time for hobbies...

hello every1 i need a cw transceiver for 20m i.e 14mhz or even more if
available ......
it could be of any brand or even home brewed but working.....
it could be from 1to 50 watts.............
if any 1 has a cw transceiver to sell then i am there to purchase
it....
thanks
shubham tiwari.......

Dave,

I will need to check the SWR again this weekend. I rotated the position of the loop and the SWR did change. On 75M the 3:1 SWR was about 45 Khz, the 3:1 was around 20Khz on 40M. There is a wire fence less than 15 ft from the antenna as well as a porch 20 feet. I know there are losses as can be expected. I am pleased with the overall performance.

I am now building another 2 loops, a 6 ft diameter octagon to cover 40/30M and a 36 inch square to cover 20-10M.

I am finding the gamma match much easier to work with than the Faraday loop. I suspect I will need to make loops bigger and smaller than the calculations show and do trial and error to find the best size.

No I am sorry to say.

My PCB was one of the originals and I do know know of source.

The reason why Bill went with "dead bug" construction was the
unavailability of PCBs.

Terry

Thanks for the reply, Andrew.

Agree that the gamma match (autoformer)is easier to tune than the sense loop, since all you need to do is move the end point for best match rather than having to deal with trying different sizes/configurations sense loops for a 50 ohm match.

The tough part of building small loops (my opinion) is keeping the loop Q as high as possible by controlling resistive losses in the system. The more solder joints the higher the loss resistance, so a circular loop (using soft copper tubing) with only capacitor connections trumps a square which trumps an octagonal loop. Probably the largest source of resistance is in the capacitor and its connections to the loop. Here a vacuum variable trumps a butterfly which trumps a split stator which trumps a capacitor with a wiper.

Have you worked out a remote tuning system for your loop(s)?

Hi Dave,
It has been my experience that a vacuum variable capacitor is NOT the ideal
capacitor for a transmitting loop. Not because it is lossy, but because you
cannot solder or weld connections to the vacuum variable. I was told you cannot
heat a vacuum variable cap hot enough to solder to it or weld/braze to it
without destroying the cap. With the prices of vacuum variable caps these days I
would not want to experiment with one this way.

So you are back to square one with a vacuum variable - you will have to use
clamp-on or bolt-on connections which will start to deteriorate as soon as they
are made. I know this from experience.

From what I can gather a homemade trombone-style variable capacitor made out
of pieces of copper tubing is about the lowest-loss variable cap one can make
in a home workshop for a transmitting loop.

Hi Todd,

I have often wondered about the clamp-on losses with a vacuum variable
and have never used one.

Regarding the trombone. From my reading it appears you have to be
careful about the dielectric between coaxial copper tubing elements,
unless you are talking about air dielectric. The reason being that
apparently not all Teflon is really Teflon; some builders have
reported high Q values suggesting high losses, presumably in the
dielectric. What has your experience been?

Hi Dave,

The best article I have found on building a low-loss capacitor for a
transmitting loop was the article " A Home Brew Loop Tuning Capacitor " in the Nov.
1994 QST by Bill Jones, KD7S.

He describes how to build a trombone-style variable capacitor with motor
drive for remote tuning using easy-to-find parts. He recommends using .005" Teflon
or Polyethylene Sheet wrapped around the inner copper tubes for the
dielectric. The .005" Teflon Sheet is available from Small Parts Inc or there is a
seller on eBay that has it cut to length.

I haven't heard about any builders having problems with Teflon sheet not
really being Teflon? You can trust Small Parts Inc. High Q values mean low losses,
not high losses. Where did you read about this?

I haven't built a trombone-style cap yet but I did build a fixed capacitor
using the Teflon Sheet from Small Parts Inc and it worked beautifully with High
Q.

If anyone is interested in the article and is not a member of ARRL I can
email a .pdf copy of the article. Otherwise someone can look it up in the ARRL
website for download.

Are actual losses something significantly measureable or just academic? If we're talking dB of loss I would be concerned but in practice if the loss is insignificant why not just strive for minimal loss?

I like W2BRI's site, http://standpipe.com/w2bri/

His results echo what many are reporting, that losses can be present and the loop antenna will still work very effectively.

Re; Capacitors, I thought buttefly and vacuum variable would be equal at the worst, considering a butterfly cap has all welded parts. In fact, shouldn't a butterfly cap be superior to the vac var since the latter has to be clamped?

The 40/80M loop using the salvaged AEA Isoloop remote var. cap works
well enough to leave alone. I did what W2BRI did with his loop and
mounted the cap at the bottom of the loop and fed the loop at the top.

One other loop tuner in progress use a butterfly cap and 12vDC 2RPM
planetary geared motor using a universal coupler to the cap shaft.
This gets mounted in a 4" drain pipe light duty PVC (not schedule 40
PVC, that thickness is overkill).

I also have a cordless screwdriver motor used to move the 'rotor'
plate of a copper clad PCB variable cap I made for an indoor loop.
This setup is similar to that found on W2BRI's website.

Although the AEA Isoloop uses a stepper motor I am not convinced a
stepper is the only way to achieve fine control. The 2RPM geared
motor is doing well enough.

I am always open to other ideas.

We use 24 volt DC gear head motors(available on eBay). They turn very slowly at 2 to 4 volts for direct drive fine tuning of variable capacitor with plenty of torque. Switch polarity to reverse. Raise the voltage to speed between bands. We use a bias-T arrangement to actuate the motor via the coaxial cable, so no extra motor control lines needed. Agree stepper motors are not needed and require more control wires plus a stepper controller.

This is easily done with a DPDT-Center Off toggle switch. I'll post a sketch of the wiring in tenorman1952 folder.

Excuse me, the folder is labeled "Loop Kits". This could be used for
reversing and off to tuning capacitor, or an antenna rotator.

I have done this for wiring "blocks" on model railroad layouts.

Hi Todd,

If you could email me the pdf file I would be grateful. I finally threw out all my old QSTs going back to 1974, which won me points with my XYL. I could not find the reference on the ARRL website. Not all of their articles are online.

Where did my info come from re Teflon? I found one article on the internet probably searching trombone capacitor on Google several years ago. Don't have a link now. Regarding not all Teflon is Teflon...this comes from some posts last year (I think) on the AntenneX Reflector, and put together with the lousy Q of trombone cap from the internet article this all began to make sense.

There is a website which demonstrates how to make a butterfly capacitor from scratch. Again no link.

Dave,

On 75M,

3:1 b/w is 30 khz

2:1 b/w is 4 khz

Better than I remembered, better than I hoped for. Calculations showed me 3.8Khz 2:1 b/w, not bad at all.

I'd have to remove the 150pF doorknob cap from the antenna to measure 40M but it's freezing outside and my fingers get numb fast so I'll leave that for another day.

Very happy with results as they are at least on 80M.

I've been using gamma matching to feed my transmitting loops with good results. I could not get a good match on a 40M attic mounted loop antenna using a Faraday loop. Next I tried using a toroid with the loop passing through once as the primary and a 2 turn loop of #14 hookup wire as the secondary connected to the coax feed. My match is now 1.2:1 across the entire 40M band. In fact the MFJ 259 analyzer shows less than 1.5:1 from 6 to 9.9 Mhz when tuning across with the variable capacitor.

Question: I've seen others using toroids to feed the loops with good results. Is there a benefit or loss of using a toroid vs. Faraday or gamma type feeds with these transmitting loops.

Hi,

I have never tried this method of feeding a tuned loop. I find your results very interesting. What diameter is your loop and what kind of material is it constructed ? Do you know what kind of toroid you are using?

In relation to your question .... I would assume (obviously I have not experimented with it) that the 'efficiency' of the toroid vs. loop vs. gamma match would to a great extent depend on the power level being fed to the antenna and the nature of the toroid transformer. On a low level basis ... eg feeding the output of the analyzer to the input you are experiencing excellent coupling. However once you start increasing the injected RF power to QRP level and then higher ... I would expect the efficiency of the 'transformer' would be tested. Certainly once the Toroid reached it's saturation point the match would change and SWR would increase. How far you can go I would think would depend on the nature of the toroid and how it is coupled to the loop.

I would be very interested in the results of such experimentation .... maybe next summer I will pick up some toroids and experiment out on the deck hi hi.

Something seems amiss here. I would think that a broad bandwidth in what should be a hi Q parallel resonant circuit suggest very high losses; perhaps your toroid is soaking up most of the energy from your antenna analyzer much like placing a resistor across the analyzer.

I have no personal experience with toroid matching, but may look into it when the weather warms up a bit.

The toroid is from one of my unbuilt balun kits, it's about 2 inches diameter, and the kit directions claim 300 watts capability. I don't plan to run more than 20-50 watts through it and most likely 20w max for digital modes.

The loop diameter is 8ft and the loop material is 1/2 inch heliax.

I don't think it is broad band in the sense of low SWR w/out retuning, the tuning cap needs to be retuned for the desired center frequency. The toroid seems to match to 50 ohms much better than the Faraday loop did. It may be the Faraday loop should have been cut larger than the 1/5 diameter of the main loop but it was easier to slip on the toroid transformer. The toroid originally had 1 turn on the secondary but the SWR was still > 3:1 and adding the second turn got that down to under 1.2:1 in the 40M band. It rises slightly in the 60M and 30M bands but never exceeds 1.5:1 once the variable cap. is retuned.

The capacitor is a butterfly type but the stator plates are not welded together and I am afraid there are losses in the spacers between the stator plates. It is a typical butterfly cap found in high power antenna tuners. The final tuning cap will be remotely tuned and will be made using copper clad boards in split stator fashion.

I suspect the 60/40/30M attic loop is being affected by surrounding metal and wires but I felt like experimenting with both a ground mounted and higher loop for side by side comparison.

I think it worth experimenting with these toroids. I will search and post an inquiry on antennex.com as well as run this past some of my previous broadcast engineering associates.

In the meantime it's worth perusing:

http://www.dxzone.com/catalog/Antennas/Loop/

Some of the loop links there used toroids for feeding loops and they claimed success.

My first thought when I saw the rock bottom SWR was 'there has to be a catch'. I'm still not convinced there isn't. As long as I don't saturate the toroid I imagine it has to be effective.

You should also find that the toroid makes the antenna more sensitive for reception. The toroid couples much more efficiently to the loop than does another small loop. The only (possible) downside is the impedance inserted into the loop via the toroid. That could reduce the loop ³Q², but it should still be an overall better antenna even with the reduced ³Q². You can make a simple measurement to calculate the inserted impedance. Put a wire through the toroid with a known current at the frequency of interest. Measure the output potential of the toroid windings into your receiver. The ratio of that potential to the current is called the transfer impedance, it has units of Ohms. Divide that transfer impedance by the turns ratio of toroid secondary windings to primary, and you have the impedance inserted in the loop. So for instance if you get 10 mV out of the toroid when passing 100 mA through it, the transfer impedance is 0.1 Ohm. If you have two turns wound around the toroid, your turns ratio is 2:1, because the wire going through the toroid represents a single turn. So in this case the inserted impedance would be 0.05 Ohm, which would be negligible relative to disturbing the Q.

Andrew; I'm a student of loops, but only from reading at this point.
You are not the only one on the planet with a 1.2:1 loop. Perhaps the
only on on this board though! Seems making a workable transmitting
loop is a bit of art and science. I am interested in the toroidal
coupling method too. Efficient coupling & low SWR - the illusive
combo. Would you take pictures?

Can someone give me somemeasurement for a X frame edge wind loop that they have tryed and work. Also the number of turns and space in between turns. I've order a couple of turning capacitors range of 10 to 365 pf from Xtal Set Society and should be getting them this coming week. In the meantime I can start construction on the frame.

For the AM Broadcast band, aka MW, the crosspieces of the X can be made 24" long, which would be the form for a square loop that measures 17" on each side. Make it 2" wide. 15 turns at 1/8" coil spacing. I used 22 gauge magnet wire, and 10-365 pf tuning cap.

You may also add a one turn pickup loop in the middle or just inside of the main loop to feed an AM/FM stereo tuner that lacks a built in ferrite core antenna.

Hi Andrew,

It is a good size small loop .... just under .25 wavelength and should be quite efficient. Working such a loop on the deck should be easy ... putting it up and out of the way of surrounding objects makes remote tuning a necessity and introduces a whole different demands on one's skills hi hi. I admire those home brew adjustable capacitors I see on various web pages. From what I have read of these experiments the distance from ground (ground effect) seems to have minimal effect on radiation efficiency of small loops .... as the loop gets larger I would assume the ground effect increases.

I understand what you said the first posting vis-a-vis reasonably low SWR across 60/40/30 .... e.g. reasonable SWR when the loop is tuned to resonance. I would be very interested in the results you achieve when you start feeding power to the arrangment .... especially when you get up past 10w.

Thanks for the info.

Jim, VE3CI

Hi,

I have a small rectangular (11"x 14") edge wound loop tuned with a 10 to 365 pf capacitor that I use to 'soup-up' my portable AM receiver. It sits on a wood base that also holds a small receiver that couples by induction ..... when I move the loop on the table for best reception the radio moves with it as a single unit.

The edge wound loop consists of 16 turns of insulated hook-up wire close spaced, supported at the 4 corners of the rectangle. After winding the coil I formed a basket weave by inserting short pencil size dowels at about 3" intervals. This basket weave achieves 2 things .... first it tightens up the loop turns and second it reduces the inter-turn capacity of the loop. After putting in the dowels to form the basket weave I varnished everything in place.

It tunes from a below 540 khz to about 1300 khz. My capacitor has 3 gangs ... although I only use 1. I am sure that if I trimmed a bit off the loop and used a switch to bring in an extra capacitor I could make it tune the whole range 540-1700 ... however it works fine and I never really use it past 1000 khz.

I use the loop for daytime DXing .... heh ... at night the band goes wild anyway hi hi. I am blessed with NO local AM broadcast stations (everything local is FM)... the nearest AM station is over 100 miles away. The small loop in conjunction with a small receiver gives me 6 stations at comfortable listening level and at least a dozen more I can identify. Without the loop there are only 6 I can even identify .... and only if I use my best AM receiver ... and non that are comfortable listening level.

Just as an add-on. I can use the small loop as an antenna tuner for coupling a long wire. When I am out in the garden ... I can clip a random wire ... e.g. 40' long to one side of the loop and another piece of wire or ground to the other side. This has the effect of adding substantially to reception. If I clip the same wires directly to my SRIII (which has an antenna/ground connection) there is little benefit.

So depending on the size of your rectangular loop the number of turns and spacing will be a matter of experimentation ... my loop will give you an idea ... or starting point. Don't make it permanent until you are comfortable with the arrangement.

Jim

I moved the loop to the far side of the attic where there was much
less metal. The SWR went to 1.4:1 but most important the 2:1 SWR
bandwidth is now at 40Khz which is what the calculations say it should
be for an 8ft diameter loop made of 1/2 inch heliax. It was much
wider at the other side of the attic where wiring and A/C ductwork
must have affected the loop.

I took pictures and will post them in the photo section under Toroid
Fed Transmit Loop.

From: Tom
Topic: 4699 Message: 4699

Hi Loop Group,

I've just joined the Loop Antenna Group.

When I wanted an improved antenna for DX,
local transmitting and ease of tuning, I chose
to modify my inverted V into a loop.

Some would say it's a folded dipole, but I call
it a loop.

The best DX contacts in the 6 months that I've
had it up are New Zealand and Japan. See a diagram
of my loop at http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=15454.

Has anyone out there put up a large, > 20 feet, square, multi turn loop?

Cheers.

4700. High power 40/80M loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-01-21 17:28:55 UTC
From: Rick Meyer KI6LQL
Topic: 4700 Message: 4700

All:

I've built a 40/80M transmitting magnetic loop from 3/4" copper pipe. I've home brewed a motor driven capacitor using alumina dielectric that is rated to withstand 40 kK. Actual voltages up to 30 kV can occur if this loop were driven with 1.5 kilowatts and Q is high enough. I haven't tried this yet because I am worried about corona discharges leaking power and causing harmonics, etc. Do any of you have experience corona-proofing at very high RF? I have some special RTV formulations I could use to pot parts with sharp edges.

Hello,

I am new to this group and have a main interest in vintage SW communication receivers.

I recently discovered the area of LF and VLF and want to get into listenting to those bands. I use a Hammarlund SP-600 JX-37 SW receiver which has a 95 ohm antenna input impedance and therefore will use RG62 coax for antenna connections. I am in the process of designing a box-type loop antenna using the AM Loop Antenna Calculator by Bruce Carter (http://www.mindspring.com/~loop_antenna/amloop_calc4.htm) and other information I have read. I intend to use Palomar Engineering's VLF upconverter to enable me to listen to LF/VLF frequencies on my SP-600.

I have placed a schematic of my project in the 'Photos' section here: http://ph.groups.yahoo.com/group/loopantennas/photos/view/ad87?b=1

I have several questions regarding my design. Is it a viable design given the components I have selected? I have selected the components based on parts I have or have ordered.

I would like to place my antenna in the attic on an antenna rotator (noise source?) and the tuner circuit in a box next to my SP-600 (about 25ft/8m away. Is this something that can be done if I routed the connections between the primary windings and the tuner via RG62 coax and a second RG62 coax from the antenna secondary to the VLF upconverter? (I realise RG62 has a capacitance of about 13.5 pf per foot and that I will have to adjust my capcitor values of the tuner circuit to compensate.) Is there another cable option? Or do I really have to put the tuner circuit with the antenna as most people suggest?

I realize this is a bit of a way-out first post for a noob on this forum. I also realize that my design might just be wishful thinking. I don't know a lot about electrical engineering but I know a little. You guys know far more than me on loop antennas and electronic so I want to pick your brains.

Thanks,

John

Metro;

My 2ft X frame has 15 turns of #22 solid copper with 1/8" spacing. It
tunes the broadcast band with a little to spare. Lots of gain. Nulls
are good. Q is good. It's fun.

Mark

Hi Rick,

A really interesting question ... one I have never considered .... e.g. corona effect with power. First off I never though of corona since generally speaking a loop antenna is the least likely to create this effect ... e.g. compared to a dipole or mono pole antenna. But then a tuned loop does expose that portion of the loop to very high voltages by virtue of breaking the loop and inserting a tuning capacitor of some description. Second, I never considered driving a small tuned loop with the kind of power you are suggesting ... e.g. a killowatt or more.

I would assume that 'corona proofing' the loop would entail inserting a capacitor with the ability to withstand the high voltages and at the same time provide surfaces as seamless as possible ... as you say, no sharp edges. When running power there are tremendous force fields within the loop ... I recall once many years ago when working on the tuning unit of a 8 kw VLF transmitter site a summer student who threw a rabbit (dead carcass) into the large loop/coil which immediately set the carcass on fire and blew the transmitter off the air !!

No, I don't have related experience .... but I would certainly recommend standing well back when you pour the power to it !!!

Hi Tom ... those others are incorrect, a folded dipole is still a
dipole. What you describe is definitely a loop. Behavior of RF voltages
and currents are very different between the two.

It is also wise to keep in mind that very strong oscillating magnetic fields exist in the near field of the loop, and that the near field on the 80 meter band is up to 80 meters distance from the loop. My license comes up for renewal soon and with the renewal packet from the ARRL is included FCC rules regarding maximum power levels vs frequency.

Oscillating magnetic fields cause brain cell death in rats.

Hi Tom,

That is an interesting loop .... the natural resonance would seem to be in the 75m band. I am looking forward to your performance observations after you have had some time to use it.

Topic: 4711 Message: 4711

Hi Jim, VE3CI and the Group,

My loop is in fact a little small for
the center of the 75 meter ham band.
It's fundamental is 4.000 MHz, but the
MFJ-998 autotuner adds enough inductance
and capacitance to make a good match
for my amp at 3.6 MHz. I can tune all bands from
80 to 10 meters with the loop/tuner combination.

What really impressed me about the loop
was that it has resonant peaks(harmonics) about every 2 to 3
MHz from 80 to 6 meters.....making it extremely easy to tune.
However, I can't tune the loop for 160. That's why I'm thinking
of building Mega Loop. See:

http://ph.groups.yahoo.com/group/loopantennas/photos/view/199f?b=2

I'm on 75 meters with my loop every night at 9:00 PST.
Listen on 3.840 or 3.841 depending on QRM.

The power of the loop!

Tom

Hi Andrew, N3LCW and the Group,

Sorry for the confusion. Each side is 47 feet times 4 sides which gives 188 feet per turn and then there are 3 turns to make 564 feet of wire.

Cheers.

Tom

4714. Re: Feeding transmitting loops with toroids...

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-01-22 12:28:17 UTC
From: capntripps2000
Topic: 4682 Message: 4714

I applied 100 watts to it and there was no heating of the toroid nor arcing in the butterfly variable capacitor. I fixed the tuning on 7.04Mhz for digital mode use and will run 20-30W through it max in normal use. I'm working on the remote tuning motor now to finish this project.

So far it is performing very well, MUCH better than the low dipole I have hidden in small trees 10 feet above the ground. Much better on receive (better S/R ratio) as well as better on-the-air reports switching between the two. I am very satisfied with its performance considering it is in the attic.

Hi Tom,

I am not sure what you want the multi-turn loop to do ... so it is difficult to make a comment re your question.

The circumference of the loop is basically a full wave on 60m. and will work well 60m - 10m. Adding additional turns will of course lower the natural resonance and affect the tuning/matching to the open wire feed line but antenna performance will be virtually the same as a similarly dimensioned single turn loop. The efficiency will be affected to a small degree ... e.g. same outside dimension and height (eg same capture area and ground effect) ... but four times as much wire.

Adding turns will not make the antenna any more efficient on 160m than a single turn.

The amount of work it will take to construct and maintain such a loop will be increased at least 4 fold ... hi hi.

Jim, VE3CI

Magnet wire, can it be used on a MW loop????

I have a 18"x18" edge wound loop and a 9-365 pf capacitor. I wanted to replace the speaker wire with magnet wire 26 gauge. After doing so the loop does not responde at all when turning via the capacitor. I took it all apart and put back the speaker junk wire and it works properly. I'm Baffled, can anybody explain this? Thank you so much if you can.

Magnet wire, can it be used on a MW loop????

I have a 18"x18" edge wound loop and a 9-365 pf capacitor. I wanted to replace the speaker wire with magnet wire 26 gauge. After doing so the loop does not responde at all when turning via the capacitor. I took it all apart and put back the speaker junk wire and it works properly. I'm Baffled, can anybody explain this? Thank you so much if you can.

Magnet wire has an insulted coating on it which is very hard (and hard to
see). Did you use some medium grit emery paper or a sharp knife to remove
this first. Just asking.

Cheers
Chris, Samoa

OK guys you mean to say that it has an insulation altough not visible
to the eye? If so is it removed only at the ends where the contacts
will be made? Thank you all, you guys are a great help.

Yes, it has a thin coat of insulation, usually enamel, though other insulation materials are used for special applications. If not for this insulation, when used for motor windings it would short out.

As others have suggested, you can use emery cloth to abrade away the insulation. Enamel insulation can be burned off with a lighter. It takes just a second or two. Just be sure to wipe off the carbon afterwards. (And don't burn yourself on the hot wire.)

You want to remove the insulation just at the ends where the contacts will be made.

For comparatively short runs like you'll have in your loop magnet wire should work fine. If you ever want to go a lot longer you need to be concerned about the resistance of the wire. It's usually not a concern unless you're using hundreds of feet. Google "magnet wire" and you should find several online resources that will have full tables of specs for every available type.

Hi,

There is only one explanation ... you didn't form a loop e.g. the magnet wire was not making contact with the capacitor at one point. If it was forming a loop you would be able resonate the loop ... whether the performance was better or worse than before ... it would still perform ... or respond as you say.

Magnet wire has an insulating coating which must be removed to form solder joints or make contact ... emery cloth or sandpaper can be used to remove it.

Jim

Hi Tom,

Nice illustration .... however same conclusion. Adding turns to the loop making it a 'mega' loop will not change its fundamental performance as an antenna. How the antenna performs e.g. its radiation pattern will essentially remain the same. How it performs in terms of efficiency ... eg the amount of energy radiated vs the amount of power fed to the antenna might be affected ....my guess would be a decrease. On 160m.

Another way of looking at it .... if you take the same amount of wire (564ft) and made a single turn loop with 141ft to a side you would have very different 160m performance than a loop with only 47ft on a side. Now take the same amount of wire and form it into a 3 turn loop with only 47ft per side and the performance will become more or less identical to the single turn loop with 47ft on a side. The difference would be added inductance, capacitance, and resistance compared to the 1 turn loop. This would change how it matches the feed line and little else.

Any other opinions?

Jim, VE3CI

Yes, it is a type of varnish. It may be clear, tinted green, red, or a golden brown. But that is how you can wind an inductor, motor armature, etc, without the wire shorting out.

Look at the larger tuned loop (MTM Scientific) in my Loop Kits photo folder. 22 ga magnet wire.

Hi, Ernie. In the Links folder you will find links I placed for the Carver style "Ultimate" AM Loop. In the Photos in the Loop Kits subfolder you will find a photo. This loop is available as a kit from ebay seller jburns1987. All wood is cut, all parts included, but you need to finish the wood. I used a Minwax stain and sprayed on some Minwax polyacrylic water based clear finish from a spray can. The photo is my loop.

This is an untuned loop, no capacitor. It does not have the very hi Q of a tuned loop, but it works very well with most stereo tuners. It will not work well with tuners or radios that already have built-in ferrite bar loop antennas. With my Onkyo tuners and receivers and this "Ultimate Loop", from my home on the Louisiana Gulf Coast most nights I can receive clearly WSB in Atlanta to the east, WOAI San Antonio to the west, WBAP in DallasFortWorth, KMOX in St. Louis, MO, WLW Cincinnati, WLS and WGN Chicago.

I also have a MTM Scientific Loop built from the plans. The plans include plans and the tuning capacitor. I had to supply the wood, knob, wire, etc. See the link in the Links folder for prices of the plans kit, the full kit, and the fully assembled loops. I have photos of mine in the same Loop Kits folder in Photos.

My MTM Loop is modified by adding a "pickup loop" in order to directly feed my stereo receivers or tuners. With my Grundig S350DL I can simply place it beside the radio and it will work via induction.

If you just don't want to build a kit, consider the Terk AM loop and the Select-a-tenna from C. Crane, Universal Radio, and others. The Terk and one model of the Select-a-tennas have a socket to use a cable for direct connection to a stereo tuner/receiver.

Hi Jim, VE3CI and the Group,

In case one of the Loop members just tuned in, we're
writing about a doodle(never been built) at:
http://ph.groups.yahoo.com/group/loopantennas/photos/view/199f?b=2

Your absolutely right, Jim. I wouldn't expect a loop on 160, with
a small aperture, to perform as well as a large one. It may be OK
on 80 through 10 with a tuner.

It's a possible solution for those who want a loop
on 160, but don't have the space for a large loop.....
like me. There's very little experience out there on medium
sized, multiple turn loops.

There is some experience out there on small, < 4 feet,
multiple turn, square loops. Somebody needs to build a larger one.
And this is.....after all.....the Loop Group.....So why don't
I build one?

Thanks for the feedback!

Cheers.

4735. 4ft multi-turn BCB-SW loop project - feedback?

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-01-24 02:16:24 UTC
From: airchecklover
Topic: 4735 Message: 4735

Hi everyone;

I am embarking on an open air multi-turn loop project.
I've done my reading here and elsewhere and I've got my saw and soldering iron ready. Along the way, I'll take pictures and make notes and post them here.

The loop will be made from PVC. It will be free-standing so it will have T's & pipe on the ends. It will be 3.5 to 4ft diameter, will have 6 or 8 legs and will be slightly oval - or not. The criteria is two of the legs must span 19" so it can be strapped/unstrapped to a Lazy Susan. Cor B. is lending his mechanical design chops but I need input on L-C end of it.

I've read there is little difference between spiral and solenoid windings. I'm leaning toward solenoid. Good/bad thinking?

My 2ft loop uses 20ga solid copper. It keeps stretching - a royal pain to tighten. How does 18ga stranded sound? 16ga?

I want to tap the coil at one or two points to shorten the loop. I'm hoping to extend the frequency range upward. I've seen a few schematics suggesting this is possible but have not seen pictures. Anyone actually ever do this?

When sizing is completed, I'll do the calculations for # of turns and spacing and run them past the group.

OK - now for the crazy question of the day :) Anyone ever think about winding a spiral and solenoid on the same frame, tuning them separately w/ two caps? Would you get gain over using one loop?

Trying to stay warm in Wisconsin,

Mark

I'm into crazy questions too.
I think you'll have problems: 2 loops put together will interfere, the Q
gets lower....
Even if you disconnect the var cap ...

Hi, Mark & others!

I made for test purposes a tripple-loop for some time ago. It consists of a spiral-loop, a coaxial-loop and a copper-tube-loop. I tested it and found out, that it really wasn't a bad idea at all! Because I have been home-brewing more aerials from month to month afterwards, this forementioned one has been hanging since at my window. Only occasionally have I been retesting it, and found out, that if I add an antenna-amplifier after an Antenna Tuning Unit to it, it will give my RX240 as strong a signal as any one of the other (7!) antennas on my roof of the 4th level on my house!!!

schematics suggesting this is possible but have not seen pictures.
Anyone actually ever do this?

When sizing is completed, I'll do the calculations for # of turns and
spacing and run them past the group.

OK - now for the crazy question of the day :) Anyone ever think about
winding a spiral and solenoid on the same frame, tuning them

Jay thank you and all in the group so much. As you said the trouble all along was that (and your gonna laugh) I fail to remove the enamal coating at the contact points for the magnet wire I used to make the coil. So once removed and contact made w/ capacitor all works great. Will post pics soon.

I agree with all the previous replies ... but wanted to suggest one other possibility, though unlikely:

Could it be something other than magnet wire, with no coating?

If it looks shiny metallic, it might be a tinned wire without insulation, in which case the turns could be shorting to one another.

But I'd put my money on the enamel coating being the problem. Easy to tell by getting a meter and measuring for continuity.

After burning/scraping off the insulation, use a soldering iron and tin the ends, to keep them from corroding. If the solder won't flow and stick, then you've still got some junk on the wire.

Compared to speaker wire, magnet wire would have (a) more resistance, and (b) more self capacitance turn-to-turn, so it might not resonate the same.

Andy

Hi Guys
I Have played with large transmitting antennas for many years for SWL and HAM, we are now moving in to a retirement village so no more outside antennas and I would like to know if any of you guys have had experience with a MFJ-1788 loop antenna using it outside of its designed transmitting Freq. for SWL.
I am malty skilled but will not be able to home brew and do not know of any other good hobby loop antenna that I can use for RX and TX.
Before I lay out my money, any suggestions would be appreciated.
I now live in West Sussex UK
Regards
Tom

Actually, if it's stranded speaker wire, the speaker wire may have more resistance at frequency. Stranded wire is not a good choice for RF because of the skin effect. With the strands in electrical contact, it acts like a single wire with grooves cut in it. The skin effect causes the current to be limited to only the highest outer portions, since it acts like a grooved wire it therefore has a smaller equivalent surface area, so the resistance at frequency is higher.

So lower Q for a given wire gauge. Therefore litz wire has separately insulated multiple strands.

Of course, it depends on the relative gauges. A large diameter stranded wire may out perform a very small single strand magnet wire.

I recall (I may be incorrect) some here testing several types of wire and several different Q for BCB receiving loops and I thought the end result was that it did not make much difference. Please correct me.

And self capacitance will depend on spacing. It is usually not a good idea to simply wind the turns as close as they will go, better to space them to limit self capacitance. In which case, if you compare, say, 0.1 inch spacing (center to center) then a larger stranded wire will have a higher self capacitance than a smaller magnet wire, simply because there is a larger surface area for the larger wire.

Check out some of these other links from folks who have built these
for HF.

http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=9042

http://standpipe.com/w2bri/

Some simple programs for loop calculation here:
http://standpipe.com/w2bri/software.htm

The loop calculator shows that antenna efficiency is directly related
to the diameter of the wire used. 3/4" copper pipe seems to work well
for HF loops.

Here's some AM loop antenna stuff:

http://www.mindspring.com/~loop_antenna/

Braided wire, including coax shield that is not silver-plated, can
also become a very poor low-Q inductor as it ages and should be
avoided. I learned this while making Q measurements on coils. I was
using copper braid for connections to the Q meter, and the coils were
showing very poor Q. After replacing the short section of braid with
a flat copper strap of the same width, the Q measurements of the coils
improved dramatically. Magnet wire with a varnish coat would be much
less subject to oxidation and Q deterioration with time and might be a
good loop material. It is available in almost any size desired.

Hi Tom,

The MFJ-1788 small loop is designed to operate between 40 and 15 meters. Above or below these bands signals will be very significantly attenuated on receive, and the SWR on transmit will become too high to be useful.

Hello Tom and the loop Group,

If you can get up to the upper corner of your ceiling and tape a white wire with white tape, then you can install an apartment loop as big as the entire apartment or largest room. I would use a 4:1 balun and a tuner in the mix as well.

Yes, it won't have any angular adjustment, but it will be easier to tune for all bands.

Careful on the ladder or let a fellow ham install it for you. As we know: "H. A. M." means "Helping All Mankind".

Cheers.

Hi,

With magnet wire you basically get what you see. When winding small coils, like front-end inductors for a home brew receiver, I often use ordinary solid hook-up wire. The advantage is that the plastic insulation provides some separation of turns by virtue of the thickness of the insulation. In addition the wire is ready for soldering. If you need a heavier gauge wire then hook-wire is out of the question.

With braided wire ... eg shield removed from RG-8 cable for example is deceptive. I know I at first thought it would be a great conductor in RF circuits ... eg. connecting a feed point to a feed line etc. I have since discovered this is not true .... once it is stripped from its underlying cable .... eg looses its circular shape .... it is greatly deteriorates as an RF conductor. If you take a piece of intact RG-8 and simply use the whole thing as a conductor it is pretty good (eg you can make a loop from whole cable) although not as good as the same size solid copper. However when you strip the shield from the cable and use it alone it is not any better than solid #14 copper wire .... or I suspect ... worse.

For construction of low frequency receiver inductors you can't beat Litz wire. It is possible to build small inductors with much higher Q than is possible with magnet wire. If you want to see examples of these kinds of inductors you can google one of the 'crystal radio' web sites. These MW crystal receivers require very high Q circuits in a relatively small size in order to squeeze the last drop of energy out of the antenna (usually a random wire). These circuits are not antennas in themselves. If you want to build a MW loop antenna (when does a tuned circuit become an antenna hi hi) then the size of the inductor (capture area) becomes as significant as Q .... although Q is still very important.

Jim

For a simple electrical circuit, Q also (unless I am mistaken) works out to equal the ratio of reactance to resistance, of a series equivalent circuit.

For example, a coil has so much inductance and so much resistance.
Inductive reactance (XL) equals inductance times frequency times 2 times Pi.
Q = XL / R. The less effective series resistance, the higher the Q.

Energy is stored in the reactance part. Energy is consumed (dissipated) in the resistance part.

Andy

Dean: I picked up a box (maybe 15) of used whips from a guy on eBay.
Under $10. Keeping checking eBay using terms like 'whip antenna'.
These things come up every once in a while. Or if you live anywhere
near a ham radio swapfest (google around to check), go! You'll
probably find not only find whips but just about every other part
known to mankind :)

Aimo; In practical terms, the Q of a circuit refers to bandwidth of that circuit. If the Q is low, the circuit will have a wide bandwidth. If the Q is high, a narrow bandwidth. OK, now you know the math and where to use it, and what it means :)

Hi Aimo,

There are some good definitions of Circuit Q. The performance of different circuits with different levels of Q is roughly like this:

A low Q circuit when tuned will have a low level of voltage (signal increase) as it approaches resonance with a poorly defined peak. In terms of frequency selectivity it will be broad. Comparatively speaking a High Q tuned circuit will attain a much higher level of voltage (signal increase) as it approaches resonance with a well defined peak. In terms of selectivity it will be sharp. When building circuits in various devices how selective the tuned circuits should be is a matter of design ... as they can range from very low (broad) to very high (sharp/narrow).

If you are designing a loop or tuned circuit to pick up faint signals or you are building circuits such as crystal set receiver where you have no amplification and need all the natural gain you can get then you go for the highest Q. Such a receiving loop or circuit is very sharp with a very defined peak and will maximize the RF signal voltage that goes to the receiver/detector.

Some others in the group have pointed out the different aspects or components in a circuit that contribute to circuit Q.

I hope that helps Aimo

Jim

Thanks!

By the way, did I call myself a newcomer? I've been in this group since 2004 reading almost daily members' email and taking part in many other groups also rather keenly.

The 2004 ARRL Handbook, chapter 6.1 Glossary: "Q (quality factor) --- The ratio of energy stored in a reactive component (capacitor or inductor) to the energy dissipated, equal to the reactance divided by the resistance."

The Handbook tells more about Q on many pages, that above was only a general definition of the term...
The more I use that book, the less I think, that it was written only for mathematicians and other theorists, not to be read by a common man. It really contains beneficial information for us radiohobbyists. It only was not meant to be read from row to row, page to page, but using the index words as key words. It is just and only a HANDBOOK! -- NOT a novel.

I just wanted to tell people writing at this group to tell the beginners something, that they probably are not acquainted with. To use general terminology or explain the terms not known by everybody, especially the newcomers.
By this I by no means am looking for to hurt any ones feelings, just to express solicitude for those, who are ignorant.

Thank you for doing just the above, Mark!

Most friendly,
Aimo

Successful communication always involves holding in one's
mind, a model of the other's mind. Since we start out with
a very poor model of your mind, when anyone says something
that does not communicate, effectively with your mind, you
can help us by telling us what you understand and what you
do not, so we can improve out models of your mind.

Hi Aimo,

It's nice to hear there are others who read the Handbook ... I have about a dozen issues of the Handbook on the shelf with many other related books ... they are my excellent reference library hi hi.

Hi Aimo,
Please look at Photos section, PCB Fractal Loop Antenna Album; I
uploaded a picture of a plot for you. The plot depicts the response
of a Band Pass Filter centered at 7MHz with strong attenuation on
3.5MHz and 14 MHz adjacent amateur bands. On the left side, 3.5MHz,
you can see a strong notch of attenuation, that coil has a Q of more
than 200. On the right hand, 14MHz, the notch is almost
imperceptible. That is because the Q of that coil is poor, less than
100 or so. This is a practical definition of that Q means and its
effects.
I hope that this definition can help you.

Hi Adam,
Just I uploaded the 10m PCB Fractal Loop Antenna photo, look at Photos section. According to the theory impedance must be around 50 Ohms that means direct match, but I am not sure until finish measurements.

Interesting. I'm anxious to hear how it works.

To those interested, it's in the PCB Fractal Loop Antenna folder in
Photos.
<http://ph.groups.yahoo.com/group/loopantennas/photos/browse/dfac>

So this is an untuned loop? Or self tuned?

What is the size?

Very interesting. Have you ever tried to turn the dragon
curve into an antenna?

http://en.wikipedia.org/wiki/Dragon_curve

I once tried to make an inductor this way to eliminate any
self resonance peaks. Can't remember exactly how well that
worked.

Dear John et al

what would one expect from these extended perimeter loops

it is a way of vastly increasing the length but how does the E or H field react to it

I mean does it react locally without interference or reduced interference from nearby portions of the loop

is it some optimal geometrical arrangement that maximizes capture of E or H signal

in the end it must be something like this

best wishes

I think the fractal properties come into play only when the perimeter of the loop is on the order of the wavelength in perimeter. The fractal pattern is supposed to damp sharp resonance and broaden the frequency response or the radiation pattern, or something like that. Very small loops just have a blurred, average effect based on inductance, resistance and area, I think. But I am no expert on the effect.

4770. Question Re Single Turn Loop Antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-01-30 15:08:31 UTC
From: msznh
Topic: 4770 Message: 4770

If I build a single turn loop antenna, circular in shape and measuring about one yard in diameter, would that be seen by a wide band amp or receiver input as a High or Low impedance?

I'm not talking about a electrically closed loop. The loop would have a break where you would connect the 2 output leads. This will be for indoor use so the lead line between to loop and the WA-50 would be next to nothing. The frequency I'm interested in is the standard 3-30 Mhz SW.

I'm thinking about building one and feeding it to a RF Systems WA-50 wide band amp which has a 50 ohm input. I want to know if I can feed it direct or am I going to have to buy/consruct some sort of matching circuit.

Would appreciate any comments or input.

Tom

Tom,
I wrote a 2-part series of articles on active loop antennas in the Jul/Aug and Sep/Oct 2003 issues of QEX that should answer the questions that you have. I can send them to you if you're interested.

There's lot's of online information for beginners,
I recommend them to read it for themselves
we shouldn't need to wean them all personally.

Even the ARRL HANDBOOK 2001 is (or was)
online, though it probably shouldn't be (and
RSGB Handbook 8th edition was, though that
has now definitely gone.)

Indeed, in a previous post I recommended the
Google searches for the ARRL Handbook and
Antenna Book - but nobody reads the archives,
(considering what goes into them, I don't blame
them), which is why we are now training
everybody every time from first principles.

And in this case, giving three out of four definitions
of Q, two of which are abstract ratios and the third
of which would be of more obvious relevance stated
in another form than bandwidth.

>I just wanted to tell people writing at this group to tell the beginners
>something, that they probably are not acquainted with.

Like, for example:-

* keep line length to 65 characters or less
to allow for tidy, legible quoting;

* NOT to top post without trimming your
quote savagely; (since it is then too late
to be claimed as necessary context ;-)

Rather than quote it all - double spaced
and with unintelligible nesting, like this:-

> > > > For a newcomer it would always, every time, be good to tell,
>
>what for
>

> > > instance "Q" means...
>
> > > > Q= QUALITY, but what kind of quality?

...and then...

* NOT to follow up with about 100 lines of
this kind of garbage, (which I believe is some
part of the Yahoo web page formatting and
doesn't belong in a reply at all):-

>#ygrp-mkp{
>border:1px solid #d8d8d8;font-family:Arial;margin:14px 0px;padding:0px 14px;}
>#ygrp-mkp hr{
>border:1px solid #d8d8d8;}

(In case readers don't see that in your copy,
it was enclosed in HTML comment tags,
so it probably isn't visible in HTML email.)

Len: All good points. However, I believe the hash and trimming is
being caused by software problems, not user negligence. I believe
using the "reply to sender" link at the bottom of a Yahoo Group digest
email generates double spacing and hash. The best way around the
unwanted hash & text is to use the "reply via web browser" link.

Thanks!

By the way, did I call myself a newcomer? I've been in this group since 2004 reading almost daily members' email and taking part in many other groups also rather keenly.

The 2004 ARRL Handbook, chapter 6.1 Glossary: "Q (quality factor) --- The ratio of energy stored in a reactive component (capacitor or inductor) to the energy dissipated, equal to the reactance divided by the resistance."

The Handbook tells more about Q on many pages, that above was only a general definition of the term...

The more I use that book, the less I think, that it was written only for mathematicians and other theorists, not to be read by a common man. It really contains beneficial information for us radiohobbyists. It only was not meant to be read from row to row, page to page, but using the index words as key words. It is just and only a HANDBOOK! -- NOT a novel.

I just wanted to tell people writing at this group to tell the beginners something, that they probably are not acquainted with. To use general terminology or explain the terms not known by everybody, especially the newcomers.

By this I by no means am looking for to hurt any ones feelings, just to express solicitude for those, who are ignorant.

Thank you for doing just the above, Mark!

Most friendly,

Aimo

> > > Q= QUALITY, but what kind of quality?

Aimo; In practical terms, the Q of a circuit refers to bandwidth of

that circuit. If the Q is low, the circuit will have a wide bandwidth.

If the Q is high, a narrow bandwidth. OK, now you know the math and

where to use it, and what it means :)

Mark

4775. Re: [loopantennas] Re: Magnet wire, can it be used on a MW loop????

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-01-30 23:52:50 UTC
From: aimo ruoho
Topic: 4775 Message: 4775

THNX, Jim!
I must admit, that I only have 2, 1977 and 2004 + RADIO Handbook, 16th Edition by William I. Orr, W6SAI.
Most of the information goes far above my ability to understand, but now and then I go back studying them. It would be nice to be able to put into practice the good advice given by so many experts!
I enjoy homebrewing some simple things now and then. There's a lot of fun to manage to "put life" into new things, that you built yourself, isn't it?

Best Regards from Ami to you, Jim!

Hi Aimo,

It's nice to hear there are others who read the Handbook ... I have about a

dozen issues of the Handbook on the shelf with many other related books ...

they are my excellent reference library hi hi.

Jim, VE3CI

Successful communication always involves holding in one's

mind, a model of the other's mind. Since we start out with

a very poor model of your mind, when anyone says something

that does not communicate, effectively with your mind, you

can help us by telling us what you understand and what you

do not, so we can improve out models of your mind.

Hi Aimo,

Please look at Photos section, PCB Fractal Loop Antenna Album; I

uploaded a picture of a plot for you. The plot depicts the response

of a Band Pass Filter centered at 7MHz with strong attenuation on

3.5MHz and 14 MHz adjacent amateur bands. On the left side, 3.5MHz,

you can see a strong notch of attenuation, that coil has a Q of more

than 200. On the right hand, 14MHz, the notch is almost

imperceptible. That is because the Q of that coil is poor, less than

100 or so. This is a practical definition of that Q means and its

effects.

I hope that this definition can help you.

73s

Juan, M0WWA

Hi Steve,
The aim of the project is put into practice some of the scarce literature that I found related to built fractal antennas. The fractal loop was calculated for 28.5MHz, ¼ wavelength, three iterations and 0.8 indentation to fit in a DIN A4 sheet, printer size.
Papers explain that must be self tuned with Z between 30 to 100 Ohms approximately, can be matched directly into 50 Ohms and with 3 iterations its behavior became narrow band.
I am preparing my rigs to test all that, I will tell you results.

4781. Active Ferrite Rod Antennas

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-01-31 18:01:18 UTC
From: Chris Trask
Topic: 4781 Message: 4781

I just finished redesigning Lankford's complementary push-pull amplifier
so as to delete the 2N5160 transistor that a lot of people were complaining
about:

http://tinyurl.com/2k63ok

Now, I think it's time to take a close look at active ferrite rod
antennas. I have quite a bit of information available about these, but not
necessarily everything, and I'd like to avoid reinventing the wheel, even
though I have a particular design in mind. What has been floating around
lately about this form of antenna?

Thank you so much Chris!

You really were very fast to make your plan!
I had to make a print-out of those 7 pages to be sure,
that all of it would be handy to read through as many
times as needed.

You set a nice example to be followed in the future:
NEVER, EVER, TAKE ANYTHING GRANTED!
Never stop thinking about other possibilities!
There will always be an alternative...

What I am waiting for eagerly, is a constructure-drawing
of your plan. Perhaps someone else will have the time
and interest to make one, so that we-not-so-skilled-ones
might be able to build "A High Dynamic Range Amplifier
for Active Short Monopole Antennas"?

One more question: Could it be a bad idea to test it with
a small loop of 30/40" or so? Still a "Monopole Antenna"
would be a short vertical?

Thanks again and Best Regards from Aimo.

For a loop antenna, you might be better off looking at the low input impedance amplifier I designed with remote tuning that appeared in the Sep/Oct 2003 issue of QEX.

This is something that would best be done on a formal PCB. I have the software to do it, but having them made is a bit costly even for a 2-sided board. FAR Circuits doesn't do plated-though holes.

Understood.
We have to wait for someone to build the Amp
first and then send a photo to the corresponding
department down on this screen. A clear enough
drawing, made by free hand even, would help us
to localise the parts in a sensible way...
How about the "Manhattan style"?

Thank you, Chris!

I could come up with a sort of sketch for a layout. I'm doing a schematic capture for this, and I need to do one so as to sort out the best parts locations.

On the design of ferrite rod inductors themselves, there is a very
interesting web page at:
http://www.bentongue.com/xtalset/29MxQFL/29MxQFL.html
Otherwise I am not aware of anything particularly new.

Two fairly obvious questions probably should be asked:
1. Do you need an amplifier?
2. If so, how much gain do you need?

IIRC, possibly from one or more of the articles by Dallas, then the
performance of a ferrite rod antanna is approximately equal to that of an air core loop
of the same basic dimension, ie a 6" rod has the same performance as a 6" by
6" loop. Take a look at the Dallas files and see what he had to say about 1'
and 2' loops and the amplification they need.

Chris,

Thanks for bringing up this topic. Regarding the input impedance for a tuned ferrite rod antenna preamp -- Don't you want fairly high impedance to not kill the tuning Q? If so, what would be considered "high enough" input impedance?

I recently assembled a large multi-rod antenna with contra-wound litz-wire windings for NDB listening -- so your thread really comes at a good time for me! Right now, I use varactors to tune it and I put together a little preamp from an OPA656 wideband op amp (Av=6, non-inverting config). Even with the Hi-Z preamp input, I get the feeling my Q isn't so high -- at least not as high as my 1m air loop.

I'll see if I can get ahold of your QEX article (though i'm not a ham).

4794. Shielded multi turn loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-01 11:08:57 UTC
From: dxnature
Topic: 4794 Message: 4794

Hi all,

I like to construct a multi turn shielded loop with RG6 coax. I have already a cross section frame with sides of 1.5 meters or 6 meters per turn. I have a coil of 100 meter RG6 standing aside to use.

My frequency range will be from 150 to 500 khz. Can I make a direct coupling with the transmission line or do I have to make a single turn coupler link. I like to use varicaps to remotely tune the loop.

How can I proceede?

Greetings,
Ron
ON3RON, DXA64

The original question was for a loop antenna, not a ferrite rod.

That's a very interesting web page, especially his remarks towards the ed of part 5 concerning the spacing of the wires increasing the Q of the inductor. I knew this to be so with air-wound solenoids and multi-turn loop antennas, but until now had not seen anything definitive about inductor wound on any sort of magnetic core.

>

Yes.

>

At least enough to overcome the loss of signal due to the small size of the antenna (antenna aperature). The trouble I see, though, is very similar to all of the problems I have encountered looking at amplifiers for other types of small antennas, which is that the designers are mainly interested in maximizing the signal gain and giving little attention to the NF of IMD performance of the overall design.

I've already published my own work in the area of loop antennas, with more to come.

Looking at the various patents concerning small active antennas,
especially ferrite rod antennas, it appears that there is more than just a
little room for improvement. I've seen a couple that are fairly good
approaches, but they are potentially unstable.

I did note that the material at the end of part 5 was based on simulations.

Somwehere I recall reading that the Q of a coil on a ferrite rod was improved if the spacing between turns equalled the diameter of the wire. Looking at the figures in Table 7 shows that this situation gives most of the possible improvement, ie from 130 to 388, with the maximum obtained being 432. Getting a spacing equal to the wire width can be relatively easily done by winding two interleaved coils along the rod, and then removing one. As demonstrated, the appropriate gauge of Litz wire is far superior.

Most of the important references on ferrite loops date back to the 1950's. I will look at what I have.

Mark,
I had forgotten all about those, as well as the BBC Engineering Reports.
There were five interesting ones in the index, and I'll have to download
them tomorrow when I have a LAN connection.

4804. PCB Fractal Loop model 1 test report

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-04 02:59:40 UTC
From: juan.m0wwa
Topic: 4804 Message: 4804

Hi all,
This is my report about PCB fractal loop antenna, model 1.
Calculations were done for 28.5MHz, ¼ wavelength, three iterations and 0.8 indentation given a total size of 210mm x 180mm, 8.26inch x 7.0inch with 1mm wide pcb tracks on glass fiber FR4 standard.
According with the scarce literature that I found related to built fractal antennas, fractal loops geometry have the characteristic that its perimeter tends to increase to infinity but maintaining the volume fill, this enlargement in length reduce the volume occupied for the antenna then its size must be smaller and impedance will higher than a classic loop, therefore easier to match to 50 Ohms, in addition with three iterations in shape its behavior became narrow band.
First test was measurements of the antenna as is without tuning components, impedance and RS-Xs, equivalent parallel resistance and reactance, with my version of N2PK Vector Network Analyzer and inductance and Q factor with L/C Meter IIB and HP 4342A Inductance/Q meter.
The measurement gave 1.78uH of inductance and Q of 50. Z and Rs-Xs are show in pictures 1 and 2, on PCB Fractal Loop model 1 test report, Photos section, no resonances were observed.
All indicates that the antenna is high reactive and so a compensating capacitive reactance must be place in circuit, picture 3, capacitor C2 only.
We can see in picture 4 that the resonant frequency is now 43.250MHz and the return loss is -39dB equivalent to a SWR of 1.02.
Because it is resonating out of the band of interest thanks to the stray capacitance, a second capacitor was introduced in circuit, C1 picture 3.
The result is show in picture 5, -50dB Return loss at 28.4MHz equivalent to a SWR less that 1.05.
I don't have experience working with loop antennas but its behavior in the shack show few interference with surrounding objects, that probably means that the magnetic field predominates.
Although first tests are promising, for field test purposes I am designing the next antenna, model 2, with more wide PCB tracks but keeping the same size.
Any comments will welcome.
Regards.

Juan, M0WWA

4805. PCB Fractal Loop model 1 test report Errata

4808. Make my own antenna selector ..

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-04 07:36:18 UTC
From: Marc
Topic: 4808 Message: 4808

Hi,

Here,
http://www.rein-hoeren.de/inhalt/496.shtml
you can see a anetnna tuner by Charly Hardt
(for sale on
http://www.charly-hardt.de/eigen.html
I think Charly ships worldwide)

I guess that with my knowledge of making loops I should be able to make
such a tuner.

But my question is: what kind of spool/ var Cap should the preselector
contain??

How large should the spool be ??

I think you can connect the mass with the power unit (the -) too,
instead of the headphone out.

Marc

Hi John,
Related to loops and even more fractal loops I am moving in unknown territory. I agree with you that simplicity is the key on designs. The main reason of improve tracks is strengthen the antenna and improve its response according with technical papers. At this early stage of the project my purpose is test if 1/4 wavelength fractal loops can work on HF frequencies, afterward if it works simplify in some way the design.
Regards.

Nice products and thanks for to Juan for making
them available but the site doesn't score well on
accessibility - we do care about the disabled now,
post-Richards, don't we?

For example, from ../page/lodestone.html:
* product illustrations with no ALTernate text
description for a screen reader to pick up;
* links to pdf-format data sheets that are Adobe icons
but the ALTernate text doesn't say so, it just gives the
part number with no clue of the change in presentation
(and probable long delay waiting for Acrobat Reader to
load) on following that link.

(I notice these things because I usually browse with
image display turned off to save data charges - but I
have the option of viewing link targets in the status
line or - somewhat laboriously - finding text-free-image
URLs in "View Page Source, both of which would be
more difficult for someone using screen reader software.)

>thanks for posting this

Why not thank him directly and individually,
instead of posting a one-liner (or in Aimo's
case, a "me too") to the thousands on the list?

This is a tuner for a high-impedance short wire antenna,
as exemplified by a telescopic or whip aerial on a
portable (or tabletop) low-cost receiver.

>I guess that with my knowledge of making loops I should be able to make
>such a tuner.

Perhaps, but the fact that you're posting this in a loop
antenna group, and asking the following questions,
makes me wonder how extensive or relevant your
experience is: this really isn't a loop-antenna project.

>But my question is: what kind of spool/ var Cap should the preselector
>contain??

Assuming 'spool' is 'coil' - lost in translation, then the
coil and capacitor should be calculated to resonate
near** the frequency of interest.

[** The exact resonance will be modified by the capacitive
effect of the short wire and also whatever reactance is
presented by the receiver input circuit.]

This 'antenna tuner' is a parallel resonant tank across the
receiver's high-impedance antenna input.

It works by resonating at the desired reception frequency,
thus boosting the input voltage by the Q of the resonance
and acting as a low-impedance shunt at frequencies away
from the resonance point.

This increases the selectivity of the receiver and helps to
protect it from intermodulation in the input stages -
'preiswerten' radios do not have the 'bullet-proof' front ends
that hams expect in communication receivers.

>How large should the spool be ??

If you mean value, then to resonate, as described above.

I note from the picture that 'something' is switched for
band selection: 3-6, 4-9, 5-12, 8-18 and 12-30 MHz.

Since these are all roughly the same bandwidth ratio,
this makes me think the the inductance is switched,
either as several coils or a tapped inductor, rather than
padding the variable capacitor with fixed capacitors.

If by large you mean size, then as large as you like.
If you make it big enough then this can truly become
a loop antenna project and you can throw away the
short wire aerial or collapse the telescopic aerial ;-)

>I think you can connect the mass with the power unit (the -) too,
>instead of the headphone out.

Use whatever makes the most direct connection with
RF ground in your receiver. Remember that the circuit
through the 'antenna tuner' has to shunt the unwanted
frequencies, so extra impedance is undesired.

Regards, LenW

A loop antenna = LC circuit
This antennatuner seems to be an LC circuit too...

Because I don't want to mess with formula alone, and want to invite
other people to think, I post it here ...

IMHO, the important reference is the paper by Van Sutchelen:

van Sutchelen, H, Ferroxcube Aerial Rods, Electronic Application Bulletin,
Vol. 13, No. 6 (1952), pp 88-100.

He wrote at least two further papers:

van Sutchelen, H, Losses in Ferroxcube Rods and Tubes, Electronic Application
Bulletin, Vol. 13, No. 7 (1952), pp 109-114

van Sutchelen, H, Tolerances and Temperature Coefficient of Coils with
Ferroxcube Slugs, Electronic Application Bulletin, Vol. 14, No. 1/2 (1953), pp 27-32

I first came across a reference to the first two of the above papers in an
article by Dallas Lankford: 'Loop Antennas: Theory and Practice', 1981, which
was reprinted in the National Radio Club book 'Loop Antennas: Design and
Theory'. My copy is dated 1995. However the references gave the title as
'Electronics Application Bulletin'. Note the plural of the word "Electronic". I recall
that this further added to my difficulty in locating copies of the papers

Another paper in my files is:

Blok, H., and Rietveld, J.J., Inductive Aerials in Modern Broadcast
Receivers, Philips Technical Review, Vol 16, No. 7, January 1955, pp 181-194.

HTH and 73

I've run across at least one of those, and I wonder if it's in another
file here? I'll have to look later. If not, I know that they're available
over at the university library.

Snelling in his book 'Soft Ferites', (1st ed 1969, 2nd ed 1988) has a whole chapter on ferrite antennas. It is well referenced, and includes the first paper by van Sutchelen, and that by Blok. Many of the references have a Philips/Mullard connection, which means that they may be very difficult to track down in the USA. Looking at the preface to the 2nd ed. it appears that Snelling must have worked for some part of Philips.

4817. Quantum QX Loop 2.0 Plus+ for sale

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-06 18:51:23 UTC
From: Neil Bell
Topic: 4817 Message: 4817

I FINALLY got permission from my homeowners association to install an outdoor Wellbrook Loop on a 20 foot mast! Therefore I am putting my like-new Quantum QX Loop Version 2.0 plus+ up for sale. It is in perfect condition and costs about $250 new, with AC power supply. If interested contact me off-list. Minimum I will accept is $175 - delivered to anywhere in mainland USA.

Great product (see www.dxtools.com) - so make me an offer.

Neil Bell

Yes, Snelling was a big honcho at Philips, as was Smit. I have the
first two editions of Snelling's book, plus the one by Smit.

From: Chris Trask
Topic: 4819 Message: 4819

I went rummaging through my various boxes of ferrites, and found that I don't have a ferrite antenna rod that is to my liking for this project, just smaller ones that I can use for a proof-of-concept. What I would really like is the 7.5"x0.5" Fair-Rite 61 rod that Bytemark sells. Antique Electronic Supply has a similar one that is 7.5"x0.375" of the same material, but I would prefer the larger diameter one from Bytemark.

I've heard various stories about buying parts from Bytemark, and before I do so I'd like to know what other people's experiences have been with them. And if anyone just happens to have one or two of those rods they'd like to part with, I'd like to hear that also.

Chris,

I ordered from them about two - three years ago and didn't have any problems. One of the orders to Bytemark replaced an Amidon Assoc. order that was momentarily lost in Amidon's system and was shipped by Amidon two months after I received the Bytemark replacement order!

I've never bought anything from Amidon, reason being that they don't manufacture anything and instead market Micrometals products. I buy all of that material and most of my ferrites from Lodestone Pacific or Eastern Components. I've also bought from Kreger components in cases where he has stock on an item that nobody else has. He's an interesting fellow, and I will probably use him again in the future as he helped me out of a short-term parts problem once.

I had heard of some problems with ByteMark in the past, but nothing recently. I want to buy a pair of those roids for this project, and I'll probably do so after I've put together a protype for the amplifier circuitry using one of the short rods that I have available.

Neil -- DO NOT sell it... YOU WILL BE SORRY someday. Selling this
sort of thing is like selling your little brother to the Gypsies...
after awhile you will miss him and want him back.

Also, you may find that the Wellbrook does not do better at 20 feet
and may work better down at, say, ten feet. Contact Andy at Wellbrook
about this before assuming higher is better in all cases.

Nice of the association to concede. They must be fairly progressive
and you must be fairly persuasive and diplomatic.

I think you will miss using the Quantum on MW in many cases as the
Wellbrook may not be better in all situations - even though it does MW
and SWL bands. It will be better on SW as the Quantum cannot go
there, but I would not trade either of my Quantum or Wellbrook antennas.

//////////// Just MY take... Richards - K8JHR ////////////

Dear fellows:

I looking for the schematics (electronic diagram)for the Ramsey Magnet signal antenna.

I think that will very good idea to shield the ferrite loop to erradicate the EMI and the noises, anyone have tested this antenna?

I see that one colleague of thi forum made some modification on the antenna, can he share with me their impressions?

best regards

Jorge Morales Mello

I had one once and it was very good for MW broadcast. The shield has a narrow slot that runs the length of the rod and faces down. It is also grounded. I tried to make it work on LW but could not find the right combo of components to make it work. Someone else did but they did not share the values - and # of windings.

Unless someone has already worked out a formula, it may be a bit of cut and try. There is at least one Javascript on a website in the Links section (also mentioned recently, search for loop calculator in the archives) that calculates with a fixed spacing. You'll also have to take into account capacitance of the cable, there's where the cut-and-try comes in.

I went and looked it up, here's Bruce Carter's javascript loop calculator. Uses turn spacing rather than loop width. Enter values, guessing at minimum capacitance, then calculate cable capacitance and use that to get a more accurate guess at minimum capacitance, repeat 'til the values don't change.
http://www.mindspring.com/~loop_antenna/umr_emc_calc.htm

I would think a single loop coupling would be better than a direct connection. Less affect on loop capacitance, less loading of the tuned loop.

Jorge,
I will try to find the schematic that came with the Ramsey and post
it. The stock shielded head performed reasonalbly well. The mod that
I made performs very well, (see posts 655 and 686 for the details).
As I recall, there were some high tension lines in the vicintiy that
it dealt with better than the CCrane Twin Coil. The kit comes with a
wall wort that delivers the necessary supply, 22 volts I think. I
seriesed 3 - 9 volt batteries together for portable use. Speaking of
mods, I also modified a Degen 31 to accept a ferrite loop head with
good results - it was a "custom wound" smaller ferrite loop head as i
was thinking portability and price. For use in the MW band. I posted
a picture of it in another loop group. This link proabably won't work
but you'll get where it is.

Ron,
What you are envisioning sounds challenging and could present some
problems to fuction effectively in a remote application. I have
entertained the thought of using remotely tuned amp such as the
Ramsey signal magnet with a large remote air core. Unless you are in
a truely remote location, it would be more of a noise magnet though.
Shielding the loop using coax would involve breaking the shielding at
the top of each turn. The coax that feeds the loop also supplies the
tuning voltage. The loop can be 100's of ft away. Without knowing
your skill level, employing this or something similar (like the Degen
DE31?) could be easier to realize. If anything, maybe this will
stimulate more discussion...

Regards,
John

Yeah... but Aimo is originally from ... like Sweeden, Finland or Norway or some other place very. very North and very cold... and NOW hides out in much WARMER Spain. I don't think THEY were responsible for the sinking the Maine.

No... those Northerners are more like responsible for Ursula Andres and other fine blond buxom beauties... and Nokia cell phones... The original Miss Universe - 1952 Armi Kuusela of Finland... and again in 1975 - Anne Marie Pohtamo ...it is in the sport of rallying that the Finns truly excel, as rally drivers from Finland have dominated the International rally scene for over four decades.... but I prefer the dames. ;-)

No... it just is not fair. There is no justice. So you cannot lay that on dear old Aimo...

Just MY take. /// Richards - K8JHR ///

It¹s not discrimination in a bad sense, it¹s just a recognition on the part of many that regardless of the current state of globalism and internationalism, that it is simply easier for someone in the US to do business within the US, because of shipping and also if something goes wrong and there is a dispute. It is exactly the same thing as what drove Europe to become the EU Europe was trying to be more like the US in that regards. If you have a large customer base that is easy to service and meets your business needs, why go out and try to get a few more customers, each of which costs more to service and brings along potentially more risks/costs?

Well, well, well!
Breathing is also volunteer!
I understand your valued opinion.
The lazy people may do what ever they want as long as they don't harm others...

Isn't it so, that a person in a foreign country has to pay a lot more for something, that he/she buys from another coutry? So the seller gets more from them for all extra work they have to do. I have noticed it many times, because during tens of years I have purchased a lot of things from the U.S.A., the U.K., France, Germany, China and some others. And I must have paid a lot more for things from outside Europe, except from China.
Especially when buying some electronic machines from the U.S.A. I must have paid insurance and handling costs above the mailing costs and the cost of the thing I wanted! And last but not least: I must also pay for the customs and inland courier's charges! So dependent of the piece, I purchased, the cost has often more than doubled!
So it has been all for the benefit of the selling organization, I guess - not loss!
The handling costs have usually been rather high, a lot higher than would be reasonable (MHO)! Stuped me! Right? RIGHT!

Greetings aimo!

Let me interject this about lutefisk. I didn't know either!

I Googled it and this is their definition:

[Norwegian] fish dish of dried cod, cured in lye, then reconstituted by boiling. Traditionally served with clarified butter or in white sauce and ...
also
dried cod soaked in a lye solution before boiling to give it a gelatinous consistency
and finally,
Lutefisk (lutfisk) (pronounced in Norway, in Sweden and the Swedish-speaking areas in Finland) is a traditional food of the Nordic countries made from stockfish (air-dried whitefish) and soda lye (lut). In Sweden, this food is called lutfisk, omitting the medial 'e'. ...
Not being a lover of fish, I didn't know either, and keep posting, I enjoy your point of view.

Rex in Jamestown, CA USA

I'm out again, because my thick Reader's Digest dictionary doesn't contain the term "lutefisk". (And I suppose, that either the Swedes or the Norwegians produce and love it.) Must be terrible!

Hello!
That's, what I was supposing, but because I'm not accustomed to use Google, and left my Finnis/Swedish/Finnish dictionary behind, when I moved to Spain, couldn't identify it.
My mother used to cook that white dried lye-fish once a year and called it "lipea¨kala". My mouth didn't like it at all! I must say, that I really hated it! As an adult I never ate it. In the Northern Europe it was and probably still is a tradition to make it at home and eat it during the chrismas time (or Easter day (Passover)). Perhaps my mother didn't know, how to make it more delicious? Later, visiting Indian restaurants in Spain, I've learned, that there are so many nice spices, that will kill any bad tastes! I think, that knowing that lye is poisonous, made me to be afraid of that stuff....

Thank you for your nice comments, Rex!
73, Aimo

4855. SDR-IQ works great down to DC

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-11 03:42:50 UTC
From: malucoelbejuco
Topic: 4855 Message: 4855

Hi All,

I've been playing with the SDR-IQ from RFSPACE all weekend. It is the most incredible VLF receiver that I have ever played with. The frequency response is pretty much flat to below 400 Hz (NOT KHz). I can actually connect a microphone to the antenna port and hear myself on 0 HZ USB. With a 40 meter dipole, I am hearing all of the submarine stations on the 20 KHz range. The 60 KHz signal is booming in. This receiver also displays up to 190 KHz of band on the waterfall display and allows you to record the chunk for later analysys and tuning around.

They are currently available here;

www.broadcastconcepts.com under the Software Defined Receiver section. I think they are some on ebay too. That's were I got mine.

I need to build a loop antenna for it. Need something that I can tune 20KHz to 500 KHz.

Regards,

Marko

So, if some people have hearing loss in that frequency range (20khz), is
that diue to submarine stations??
And what about dogs that hear far above 20khz? "dog at sea barking" ??

Hi Marc

It is a strange world at these very low frequencies ... at first it is hard to get one's head around the difference between magnetic waves, electromagnetic waves, and traditional mechanical sound waves even though they may ALL be at the same frequency! Each manifestation requires a different detector .... although there can be strange cross-overs hi hi.

I recall when I was a kid I built my first multi-stage high gain transistor amplifier (made from Ratheon CK721's ... if anyone can remember them) I used to make directional microphones etc. One of my experiments (modeled after an article I read in Scientific American) was to attach a large multi-turn loop to the AF amplifier input. The objective was to pick up magnetic waves in the audio spectrum that are generated by natural phenomena such as electrical storms. I picked up these 'whistles' many times .... which could not be heard directly with the ear or microphone. There was no detector in the circuit ... just a loop to a high gain AF amplifier.

Now The signals used for submarine communications must be electromagnetic waves .... the low frequency of course to facilitate transmission over long distances below water .... but I would be curious to know if my old 'whistler' receiver would also pick up the transmissions if in close proximity to the transmitter site.

I have had (when I was a kid) other 'cross-over' experiences between (magnetic generating equipment) and electromagnetic receivers. But I have not experienced cross-over between mechanical sound waves and magnetic or electromagnetic waves .... although the study of earthquake detection and animals have some interesting stories. Maybe some dogs can detect magnetic waves in the high AF frequencies ... I know some dogs seem to panic in the presence of electrical storms .... it may not be just the audio bang of thunder.

Jim

The seller doesn't get more. All that extra you pay goes for extra shipping and import duties. It's possible some sellers capitalize on the situation and charge more on export deals because they think they can get away with it, but most make the same profit regardless of where the product ends up. Those that don't sell overseas quite likely simply don't want to deal with the hassle of learning how to do it.

Getting back to the question from the OP, there's a guy on ebay (kwtubes) in Lithuania who sells a lot of surplus Russian electronics. I've purchased ferrite rods from him before. I did a quick check and he currently has some 10mmX200mm ferrite rods that were intended for use as antennas in Russian MW radios. $20 for eight of them. Shipping will obviously add a bit to the final price. I have no connection with this dealer other than having purchased from him before without incident. I was originally leery of buying from eastern Europe, but everything went smooth as could be. And he's still selling on ebay several years later.

Hi Paul,

The original post, a description of the performance of the SDR-IQ, seems to indicate that it will respond to signals (voltage variations at the antenna input) from a microphone or from a wire antenna (either through induction from a magnetic field, an electric field, or an electromagnetic field). However, if he is receiving transmissions at 20khz from a transmitter hundreds or thousands of miles away I assume it travels as an electromagnetic field. If you modulate a magnetic field only the distance you can transmit is limited to a fixed field of several hundred feet at best. I assume electric storms can do better.

We all know that you can hear electrical storms hundreds of miles away .... obviously they create electromagnetic waves with lightning. However, the detectors at the sites you quote are detecting something else in the electrical storm .... either a building electric or magnetic field, or both .... and in the case of the Whistlers' these fields may be 'modulated' with audio signals. As I mentioned I picked them up using a loop ... in retrospect it was probably not the best arrangement for detecting these signals but probably the only practical approach given the type of audio amplifier i was using.

If it is a magnetic field that is being generated then the electrical storm must be causing current to flow somewhere (since current flow generates a magnetic field). Perhaps it is some sort of plasma flow in the atmosphere in the storm area ... that takes place before the actual lightning strikes and creates the electromagnetic waves (static) we can hear on receivers hundreds of miles away.

I sell some imported items (non electronic) and have to add cost of shipping and customs. These products are made in the UK. The cost depends on what country, how far shipped, customs and other hidden (to the consumer) costs.

Sometimes people think they are getting "ripped off" because my retail price is not the same as the UK price x the current pound to US dollar conversion factor.

It works both ways. People in the UK pay somewhat more for some US made products I sell that are also imported by my UK supplier (we sell to each other and distribute each other's lines).

I think most reputable sellers want to be competitive with their pricing. I know I do. But there are many costs that must be recovered for me to bring a product to your doorstep.

As a consumer I used to get upset over cost of shipping. But not only does it cost me to ship an item to you, but if it is not well packaged, and damaged in transit, we (seller and buyer) have both lost. This requires good cardboard boxes, bubble wrap, foam "peanuts", and other packing materials. Those all cost me. Not only do I have to pay for cardboard boxes, but I have to pay shipping on the boxes to me. Believe me, there is no such thing as "free shipping". It is in the cost of your goods somewhere.

There there is time filling out customs forms, and all the other hassles of shipping to other countries. I am not surprised that some companies won't ship to other countries.

In the photos on those links, the PVC pipes house his ferrite rods.
In another section of his site he sells a number of rods and
assembled antennae for VLF use.

Anyway, thought you'd be interested in his site. There are some
charts of how many turns of wire on what size rod works for whatever
frequency. I plan to try one for AM, compare to some of my air core
loops.

Please receive my apologies!
What I ment was not, that the seller would inevitably get more profit, but he gets more paid for his work in the final sum. Understood? There is a small difference, isn't there? So of cource he must earn at least as much or even more for his extra work, right?

The seller doesn't get more. All that extra you pay goes for extra shipping and import duties. It's possible some sellers capitalize on the situation and charge more on export deals because they think they can get away with it, but most make the same profit regardless of where the product ends up. Those that don't sell overseas quite likely simply don't want to deal with the hassle of learning how to do it.

Getting back to the question from the OP, there's a guy on ebay (kwtubes) in Lithuania who sells a lot of surplus Russian electronics. I've purchased ferrite rods from him before. I did a quick check and he currently has some 10mmX200mm ferrite rods that were intended for use as antennas in Russian MW radios. $20 for eight of them. Shipping will obviously add a bit to the final price. I have no connection with this dealer other than having purchased from him before without incident. I was originally leery of buying from eastern Europe, but everything went smooth as could be. And he's still selling on ebay several years later.

Hi Aimo. I have some friends who will not sell overseas on eBay. They say the extra work and chance for getting ripped off is too high to take the risk. FWIW, I sell overseas and have had no problems. I have one friend is very protective of what he sees as "his nation" and as a rule, will only deal with Americans (but he likes Canada!). He is a good friend and I have learned it makes no sense to argue with him ... he gets angry and stops calling. I like my friend - he is very smart and is a loyal friend. But he makes no sense to me: He is in love with communicating to people around the world via SWL and ham radio yet doesn't not want to transact with these same people.

Email me personally if you need help purchasing something from an "American only" seller.

Ah, now I see where you were going. The seller does more to ship overseas so he rightly deserves more in return. I misunderstood your intent.

In reality, I suspect most sellers make LESS money on sales overseas. I'm sure the larger merchants have all the costs accounted for and charge accordingly, but I suspect merchants with fewer sales overseas end up with less profit due to not being aware of how much work is required for international shipments. For small items it doesn't have to be a big deal if the seller knows the ins and outs of shipping internationally. Shipments labeled "parts" tend to get through customs with little attention and very low tariffs. But that only works for small packages.

I bought my AR7030+ from the UK. The seller told me what to expect in the way of import duties. I thought I'd made out like a bandit when UPS only wanted $35 when they delivered. Sadly, a couple weeks later I got the bill for the actual duties. The $35 was just their fee for figuring out what the duties were and handling it for me. The real duties were exactly what the seller said they would be.

I would also add that the whole "CE" requirement in Europe is a bit of a mixed blessing. It does provide some assurance of safety and quality, but they don't make it easy to get that CE mark. I know from experience at work that it's a very involved and costly process. They even charge a not insignificant amount for the documents that explain the requirements. For a larger manufacturer cranking out thousands of units it's probably not that big a deal, but for smaller businesses it can make one question whether it's worth even doing business in the EU.

Thanks for trying to comfort me, Mark!

As we easily can see, we are all imperfect... You call your friend "very smart". If he were perfect, would he have negative attitudes? So, in all his loyalness, he too is imperfect! Just let us forgive him, so that we will be forgiven, right? Perhaps he too will learn something, perhaps not. It's volantary to change attitudes, isn't it? We can't force him. But as you consider him as your good friend, I hope that you will continue keeping him as such for mutual contentment. What would life be without a few good friends? No real satisfaction to live alone...

I read about us Finns today, that too many of us are very prejudiced. Perhaps that is one of the main reasons, why I always wanted to get away from that land? In January started my 8th year of living in Spain. The mental atmosphere here is just what I like, positive and joyful!

As you told me, there always is a circuitous route! If someone is negative, perhaps there are one or more positively thinking (and acting) persons, who are willing to aid us to reach our goals?
I will keep your suggestion in my mind, Mark!

73, Aimo.

4872. great ferrite rods for sale 17cmx10mm

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-12 22:17:54 UTC
From: ehydra
Topic: 4872 Message: 4872

Hi low-frequency folks -

I managed to get a big lot of rods.

So I can give away a bunch of ferrite rods for experimenting. Great as antenna for up to 10MHz or as a wideband transformer. If you can accept a sightly reduced effective ui you can bundle them together.

quick technical data:
manufacturer: Philips
material: 3B1
ui: 900
curie temerature: 150?C
length: 170mm
diameter: 10mm
outline: rod with six cuts (Improves Q of wound coil!)

Price: Euro 18,-

Here is more info:
http://www.ehydra.dyndns.info/temp_ferrite/

And I sell LCD 2x10 with i2c serial bus connection AND backlight: Euro 13,-
It is entirely shielded in tin metal and approx. 55x30mm outline. See photo here: http://www.ehydra.dyndns.info/temp_ferrite/

Shippping is from Germany. You can pay with PayPal (ehydra@...) or bank account transfer. I cannot offer insurance for money sent by snail mail.
Shipping costs (insured) in Germany is Euro 6,-. Other countries please ask or suggest a useful carrier.

Hope this helps. Just ask if you need further info.

regards -
Henry Kiefer

Hi, group!

I wonder, whether anybody here uses a Wellbrook LFL1010!

I thought about buying one for LW and MW.
Would anybody know, how it performs on LW and MW compared to the
ALA1530 and what the usable frequency range "really" is?

Thanks very much in advance.

Hello Joachim,you can find somes measures between my Wellbrook LFL1010 and my PA0RDT miniwhip especialy on VLF,LF and MF bands.

See in pictures folder of thisYahoogroups and browse in "F4DTL test LFL1010 Wellbrook"

all measures LF/MF was realised with Icom IC7400 like receiver and screen captures from Spectrum Lab.
For VLF receptions,direct conversion with my USB Soundcard EMU 202 at 192 kHz sample rate with Spectrum Lab VLF receiver config.

Enjoy LFL1010 and best regards dear Joachim.

Joachim, I have been using an LFL1010 here since October of 2006 and have nothing but glowing admiration for it! I can only compare it a couple of coax loops that I have built in the past, no comparison, and my 160 meter inv-L antenna, beats it 90% of the time. I have it at about 23 feet AGL, on a city lot. The ability to rotate it of course helps considerably as well. Lots of noise here off and on during the night so its nice to null that out as well as the strong NDB's so I can try to make out the weaker ones underneath. It works great with the lowfer stations on 137 and 185 as well as the NDB band. Have not used it much on MW and above but it does work there. The only negative I can think of is that it does not like to be covered in snow or ice!

4877. BNC connector

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-17 09:50:49 UTC
From: C. Beijersbergen
Topic: 4877 Message: 4877

Hello,

For those of you who own a Wellbrook antenna I have a question.
Connection of the loop to the coax cable is through a BNC connector. Apparently this is out in the open. How does it stand up to rain, storm, snow and frost? Will this connection withstand this all through the years or is some additional sealing required?
No doubt some of you are having your Wellbrook placed on the roof or in the garden, unprotected from the elements. I'd like to hear about your experiences on this issue.

From: Briggs Longbothum
Topic: 4878 Message: 4878

Unless a connector is specifically designed to be weatherproof or waterproof, it must be made so if it is survive operation in those enviornments. Wrapping in "Coax Seal" or encapsulation in something like a good silicone sealant will generally be sufficient but care must be taken to make sure all surfaces are well cleaned and dried beforehand. A BNC connector, by itself, is not weatherproof.

experiences on this issue.

Any BNC connector used outside will need to be protected.

The Wellbrook loops have a particular problem in that the BNC sticks out
sideways from the plastic junction box at the base of the loop thus potentially
exposing it more to rainfall etc.

So far I've only used my loops indoors but do intend to mount them outside.
As well as sealing the connector with self amalgamating tape I plan to make
a cover, cut from the bottom of a plastic bottle or using PVC pipe, that will
shield the junction box and connector from the worst of the weather which,
on the west coast of Scotland, can be quite extreme.

As a general comment, if using self amalgamating tape outside remember to
cover it with a layer of insulating tape or similar as it can deteriorate quite
badly when directly exposed to sunlight.

I can echo that. I first tried my Wellbrook out at approx. 20 feet high, then at 10 feet and finally settled for 6 feet where it worked better than the previous 2 heights. Having said that, experimentation would be wise if possible.

I put this question up on the ALA1530 group but got only 1 reply"

How many (if any) people have
noticed any benefit from grounding their receiver while using the
Wellbrook ALA1530? I'm referring to possibly improved reception.

4884. Wellbrook ALA1530+ vs ALA330S Recommendation in Western USA

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-17 15:01:34 UTC
From: k7na6
Topic: 4884 Message: 4884

I posted the following in the ALA1530 group but, not receiving any replies, thought I would post on this more active and robust Loop Antennas group.

I am new to this group but for some time have been monitoring Wellbrook discussions on other groups such as SWL Antenna, ALA1530 and Eton E1-XM. Recently joining this group, I have read through many of the archived postings.

I live in a rather noisey suburban environment in Southern Calif. and am contemplating the purchase of a Wellbrook loop. I've nagged Andy Ikin repeatedly for information and he has been gracious and veryhelpful.

Although I had thought my choice would be the newer ALA1530S+, Andy cautioned that since I have two MW broadcast stations within about 10 miles of my home, the 1530+ (without the 10db amplification) might result in less of an intermod problem. I had thought the additional 10dB gain would be essential here in the western USA.

Currently, I am in a quandry whether to buy the 1530+ as Andy suggests, or run with the 330S for better SW performance. I enjoy SW listening but I also want excellent MW sensitivity as well. I kinda want it all.

I am wondering if there are group members living in the Western USA, where SW signal strengths tend to be weaker, who can give me the benefit of their experiences and recommendations. Will the 1530+ perform satisfactorily on SW here in the West or have most of you elected to use the 330S?

Also, I am wondering if the "S" designation on the 330S means that the same 10db amp is used in the receiver interface box as in the 1530S+? If that's the case, evidently Andy has somehow desensitized the MW coverage to improve results in strong MW environments, but this is not the case with the 1530S+.

My current receivers are the Eton E1-XM and the sub-receiver of my Tentec Orion ham transceiver. I am also thinking about the future purchase of a Drake R8B, R8, Palstar R30CC, Icom R75, or other suitable receiver for AM and SW DXing.

Thanks in advance for any constructive inputs. Much appreciated.

Vince
Carlsbad, CA

Be advised that some heat shrink tubing has a built in glue to help seal
to the PVC. Fine to use if you are installing your own connectors, a bit
late once the connector is put on the cable. BNC connectors, depending
on the design [and not the thread-on that I am aware of] do provide a much
higher degree of weather protection than most other connectors with the
exception of N connectors which are also moisture resistant. This is one
reason the US military gear uses BNC and N connectors to start with.

If you want to buy the tools for the F connectors that the SAT TV folks use,
those are relatively good. They also have a special goo that they put on the
connections to help seal them. Another plus there is that good quality
RG-6 is cheap and readily available these days.

Unless you purchase the silicone that is specifically for electrical
connectors
I would avoid that stuff altogether and buy a few rolls of Coax-Seal to wrap
everything with anyway. Small price to pay for the added protection.

Eric

> might result in less of an intermod problem. I had thought the
> additional 10dB gain would be essential here in the western USA.

this surprises me as most locations in a city have MW stations within
10 miles. Considering the Wellbrook loops are supposed to deal with
this as well as other types of interference, Andy's caution seems kind
of strange. Or perhaps I'm missing something?

Or perhaps I'm missing something?

****

likely he just wants to make it better

I have cjoy 1460 here in guelph about 1.5 miles from me so it is a real issue

I never thought much about this till Dallas Lankford and Chris Trask make this intermodulation performance I would say the domininant design factor whereas most of would have though snr and gain

but I think now the design objective importance is

intermodulation performance

snr

gain

cost is whatever is needed to achieve the above within reason

best
Paul

It's not an odd question at all !
I NEVER experienced any difference, neither a negative nor a positive one, when grounding my receivers while connected to Wellbrook antennas (ALA1530/ALA100/ALA100M/AVA100).

Hope it helps
Have a nice day

Dominique

Objet : [loopantennas] Perhaps an odd question

I put this question up on the ALA1530 group but got only 1 reply"

How many (if any) people have
noticed any benefit from grounding their receiver while using the
Wellbrook ALA1530? I'm referring to possibly improved reception.

I'm gonna take a wild guess that intermod won't be a problem with the Palstar R30CC.

I live in Fort Worth where we have some flamethrower MW broadcasters, including WBAP on 820. My interest is mainly SW DXing, not MW. Occasionally I'll hear some MW very faintly in the background when my portables (Sony ICF-2010, Magnavox D2935) are set to LW or SW, but I've never heard anything break through the Palstar R30C. Well, there was *one* occasion when I set up a cheap Radio Shack active antenna incorrectly (bypassed the shield/outer conductor on the feedline), but that was strictly spurious imaging due to the active antenna, not the radio. Hooking up the feedline correctly eliminated that problem.

Personally, if it was in the budget, I'd go for the 1530 and use the Palstar's attenuation switch if necessary. I'd rather have too much antenna than not enough.

Also - and you might discuss this with Andy - it's possible to hook up an attenuator inline with the feedline. I have an attenuating cable that I use in conjunction with my cheapo active antenna to reduce problems with spurious signals.

It doesn't help that their speccs don't seem to jive with reality ...

For instance the 1530S+ shows a higher IP2 and the same IP3 as the 1530+ which really isn't logical because of the 10db gain and Andy admits as much when he suggests the lower gain version ... This is what happens when the specmanship game is played and they don't tell you what they are really measuring, input IP2 and IP3 or output IP2 and IP3 ... We have to assume it's output IP2 and that the input IP2 will be degraded by the 10db gain of the extra amplifier in the 1530S+

If you think IP2 is going to be a problem because of nearby transmitters then the best option would be the 1530+ and if you think you'll need more gain you can add a good outboard 10db preamp such as the Kiwa Broadband Preamp 2.0 or DX Engineering DXE-RPA-1 (And I bet that the added 10db preamp in the Wellbrook is the same basic design as these two) ... You may also find that a MW BCB filter to be of use for above the MW BCB ... Kiwa makes a good 10db preamp with the MW BCB filter built in, so that might be your best option as you won't be needing a preamp for the MW BCB, your location will be way too noisy, so you can just take out the preamp/filter combination for the MW BCB

Then you can use the preamp (and BCB filter) and leave it inline and when you want to DX the BCB you can take it out ... You may not even need a preamp if you have a decent one built into your radio, for instance I have an Icom IC-R71a and it has a balanced 10db preamp that pretty stout already, not quite as good as the two preamps mentioned above (Or my homebrew versions of them) .... on the other hand my Ten Tec RX320D has no preamp and without a MW BCB filter (I took the internal one that degrades everything below 1800Khz) when I'm SW DXing it the front end will crumple from the two nearby AM BCB transmitters, not just from IP2 but from Blocking which desensitizes the entire front end

4891. MW DXing question for fellow Texans

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-18 07:12:16 UTC
From: cank13cat
Topic: 4891 Message: 4891

This is more of a location question than an antenna-specific question, but this seems like the best forum to ask...

I'm not much of a MW DXer since most US stations are all the same. It's not much of a challenge to DX a MW station 1,000 miles away only to discover it's exactly the same format as my local stations (does the phrase "Fair and Balanced" ring a bell?).

However, I've noticed that from my home in Fort Worth using only a puny indoor antenna I can easily pick up Australia and New Zealand on shortwave, along with several African stations, from the 20 meter band on up. I thought it might be interesting to see whether DXing these countries in the tropical and MW bands is feasible.

However, before plunking down the dough for a highly specialized loop, I thought I'd ask other folks who live in Texas or elsewhere along the Gulf Coast states if they've had any luck DXing, oh, say, Alice Springs. Also, has a highly direction loop helped minimize that irritating OTHR/CODAR racket that plagues the tropical bands?

(BTW, I'll be using a Palstar R30C, which has no built-in ferrite bar, and has both a Hi-Z spring loaded clip and Lo-Z SO-239 input.)

Thanks much.

Unfortunately, I can't answer for these days as I don't DX MW any
more. However, 10+ years ago, I was able to easily DX US MW stations from
halfway down the South Island here in NZ using a simple homebuilt
loop. Don't know if that helps or not.

From my home here on the Louisiana gulf coast, south of Baton Rouge, using the simple "Carver Ultimate AM Loop Antenna", which is an untuned loop of just 4 turns around a diamond shaped form, I can pick up KLVI 560 Beaumont, TX (180 miles and only 5000 w) clearly during the day.

At night I regularly pick up KBAP 820 DallasFortWorth (all one word, 420 miles), WOAI 1200 San Antonio (441 miles) quite clearly. Also WSB 750 Atlanta (487 miles), KMOX 1120 in St. Louis, MO (618 miles), WLW 700 in Cinncinatti, OH (754 miles), WGN 720 and WLS 890 in Chicago (859 miles).

My brother, who lives in the next town, with the same antenna regularly listens to a blues station in Memphis. I forget the call sign and frequency, but I can pick it up, too.

And all this is with the simple untuned loop. I can do better with the MTM Scientific tuned loop with my Onkyo tuners and receivers.

Photos of these loops are in my folder "Loop Kits" in the photo section, and I have placed other details and links in the files and links sections.

The trimmers are there to adjust oscillator tracking when used in a receiver.

In these days of digital displays it's not so noticeable as it was on tuning
scales with a pointer, but linearity of capacitor and oscillator tracking is
always a compromise and the trimmers help to get the best fit.
If, in a superhet receiver, one capacitor is used for a tuned RF amplifier
and the other for a local oscillator it's also important to have a fine
adjustment to keep them as well matched as possible over the tuning range.

That's probably because they're much lower value than the main capacitor so
would have very little effect.
The adjustments I mentioned before would be carried out at manufacture and
then left.

From: dxnature
Topic: 4794 Message: 4899

Hi Steve,

I made a conventional loop with 15 turns of wire on a 1.5 by 1.5 meter frame and 1 link coupling. It came almost on the resonated frequency I had calculated. It tuned from 700 to 200 khz. Sorry to say there is bit less noise and the signals are a bit stronger but not as I expected it to be. Ok it is a step in the right direction but I'm not content. There is still to mutch noise!!!

What I want to do right now is to replace the link coupling with a coax loop as pick-up and connect this to the feed line. What do you think? Will this give me a bit less noise?

Greetings,
Ron

JR:
Thanks for the excellent suggestions with regard to use of
external amps if needed. It appears that the ALA330S or the ALA1530+
will offer the best options for my circumstance. Andy Ikin made these
recommendations in emails that we have traded back and forth.

Mr. Ikin also sent some additional information that I would like
to share with the group to shed some light on the IP2/IP3 and
amplification issues of the Wellbrook loops:

"Reference to concerns about intermodulation performance of
Wellbrook Loops; user feedback over the past 10 years has only
highlighted a handful of actual problems with the ALA1530 where the
antennas were deployed within a few miles of multiple 50-200kW BCB
transmitters. Notwithstanding the above, the ALA1530+ was introduced a
few years ago to provide much improved MW IOP3. Also in the past 6
months the new ALA1530 has a much higher MW IOP3 compared to the old
model.

"The level Intermodulation experienced when using active
antennas; loops or Whips is dependant on the incident field strength
of the most powerful signals, the Antenna Factor and the Receiver
Intermodulation performance. Where the incident field strength is very
high the Receivers' IMD performance can be the limiting factor.

"The measured MW Antenna Factor of the ALA1530+ is approx. 10db
i.e. the loop output dBuV is 10dB lower than the field strength in
dBV/m

"Therefore if the antenna is deployed approx. 15km from 2 x 50kw
MW transmitters, the incident field strength assuming good ground is
100dBuV/m. Thus with an antenna Factor of 10db the signal level at the

output of the antenna is 90dbuV or ☐17dBm (over S9+50dB). This is the same signal level as specified in the ALA1530+ Data Sheet. So the 2nd order intermod. is approx. -110dBm and the 3rd order intermod. is ☐ 131dBm. Most receivers with inputs as high as ☐17dBm show much higher levels of intermod. compared to the active antenna.

"Increasing the antenna gain by say +10dB using an amplifier with similar IOP2/3 as the antenna, we may start to see some noticeable 2nd order intermod. providing one is using a receiver with much higher IIP2 than the antenna. Most modern receivers just can't handle multiple S9+60dB signals.

"One suggested way to achieve the higher antenna gain at HF without overloading the receiver is to fit a MW hi-pass filter between the antenna and the 10dB antenna amplifier. There can be problem with this method; simple low cost hi-pass filters don't provide the correct 50 Ohm resistive termination in the MW stop-band. Hence, the antennas' MW IOP3 can be reduced because it sees a highly reactive load. Ideally the hi-pass filter should have also have a diplexer and a low-pass filter so that the stop-band signals drive into a 50 Ohm load. However, in some situations just adding a 50-100 Ohm resistor across the input of the hi-pass filter, will reduce some of the IOP3 degradation."

I hope the above is informative. Thanks again for your suggestions. Much appreciated.

From: mhatlau
Topic: 4877 Message: 4901

For what it is worth, there are BNC's, and then theres BNC's. The Radio Shack Specials are for use inside only. They will leak like a sieve and deteriorate rapidly outside in the weather. The more expensive Mil-Spec- types are quite water resistant. For the plugs, look for the o-ring under the compression nut. Otherwise, you will have to wrap them in that rubber tape. Jacks are water resistant, I.E. if out in the rain, and on the bottom of the box, wind-blown water will not get into the connector or box (Hurricane-force winds excepted:)
Then there are the actual waterproof BNC Female connectors, good to a meter of immersion for at least an hour. Read very expensive.

One thing someone suggested is to use Silicone Rubber. DON'T. It will corrode the pins and connections rapidly, causing you a LOT of grief. The stuff that smells like Viniger do so because they emit Acidic fumes. They make some specifically for around electronic circuits, but it is hard to get in consumer quantities, and very expensive.

And yes, the rubber tape has to be protected by electrical tape.

Interesting, really!

What are the measures of your copper tube loop?
Have you cut the tube into 2 parts, or is it separated only on the lower part?
Thanks!
Aimo

I cannot see the issue here. I have the ALA-100M medium aperture loop (i.e., you supply your own wire loop about 20 feet on a side...) and I use it daily with my amateur transceiver. I often transmit on one antenna or another set to frequency, and use the ALA-100M as the receiving antenna.

Never had any problems with AM BCB stations and there are plenty withing ten miles of my operating position. I have used that antenna with cheap portables and fancy table tops and what all in between with no AM station bleed in.

Hello Aimo, Thank you for your interest. My QTH is in New York City
(lots of noise here, and this loop helps).
It's a complete 10 feet (3 meters) of 1/2 inch (12.5mm) coiled copper
pipe. Once fashioned into a loop it comes out to a 3 foot
circumference circle. Credit however goes to KR1ST at
http://www.kr1st.com/swlloop.htm. Please check it to get an idea of
it. At first I built it just like at his site and it worked fine.
Then using this as a starting point, I made another with made my own
modifications. I placed the pick-up coil on top rather then at the
bottom. I got tired of standing up to adjust the capacitor so I place
that at the bottom. The whole positioning now is upside down and
added the air variable 365pf capacitors in parallel and switch that
take me down to about 2300 khz. Doing away with the junk box am/fm
capacitor. The frame is my design and rotates for directivity. It
really is a superb loop and have logged some tropical DX with, ie: In
South America its Brazil, Peru and Honduras. In Afica it's Burkino
Faso, Mauritania, Zambia and Chad plus others.

Hope to speak again with you,
Cheers

Thanks, Paul. I'm afraid that being this far inland (Fort Worth) I'll need a more sophisticated loop than an untuned wire loop in order to exclude the US based MW stations, tho'. Another problem is the heavy QRN from local noise sources and atmospheric noise in the tropical bands and weak MW section. A well designed ferrite loop or expensive loop like the Wellbrook is probably the only antenna that'll cut through the mess for DXing beyond Mexico.

I'm just tired of US MW being dominated by the same programming - too much Foxnewsfairandbalanced-blah-blah-blah, too much Glenn Beck and his ilk, too much sports. I was temporarily excited to pick up WHO on 1040 from Des Moines, between two gospel stations on the same freq (one in Colorado, one in nearby Arlington, TX) - until I found out it's another 50,000 watt flamethrower with the same Foxnewsfairandbalanced-blah-blah-blah as my local stations.

For all I know, I might only succeed in DXing the Australian and New Zealand equivalent, but at least to me it'll *seem* interesting since it's more of a challenge.

The only interesting US based MW station I've caught recently from Fort Worth is KXTR classical music from Kansas City on 1660. Unfortunately it's swamped by yet another sports talk station. So I'd need a hi-Q loop to cut through.

Then check out the MTM Scientific. If you look at my photos you can see where I added a pickup loop to the antenna to feed my receivers. I drilled 1/16" holes just inboard, about 1/8" from the main 15 turn loop. The pickup loop is just one turn and routes back to a pair of speaker binding posts. I've used 300 ohm twin lead, though the ends are fragile, twisted pair of hookup wire, and coax. All work well.

This antenna is quite hi-Q.

You might also look at the Crane Twin Ferrite antenna. A friend has one and reports good dx from it. If you search Youtube you will find a video demonstration.

I use a clear rubbery adhesive for this. It is sold under several names and viscosities. You can pick it up in craft and hobby stores under the name Aleene's 7800. It can be peeled off for removal if required. It is not silicone, not corrosive.

I use this adhesive, and a more viscous version, E6000, for gluing crossover components in speakers, various repairs on electronics and musical instruments. It dries clear, adheres good to dissimilar materials, and has a little bit of flex, so it is not brittle like epoxy.

Would it be possible to effectively seal a BNC connector with that self-fusing silicone tape? That stuff seems to do a good job on most things, so I'd think you could overwrap the whole connection with it and be OK. All depends on the configuration, I suppose.

There's also some sort of gummy putty that I've seen the cable guys use by just blobbing it over the connector. No idea what it's called or where to get it though.

Thanks!
I have those prints of the KR1ST loop somewhere in my huge archive of photocopies.
Also I see an 8-angled (octagon) 1/2' copper tube loop parallel with my window. It doesn't have an amplifier of its own by now, nor is it equipped with a pickup-coil.
My problem is, that I don't have enough room in my shack to turn the loop around, so I have to wait for a little warmer nights to take it on my flat roof (upper patio, so to say) after I try to complete the whole thing first. It would be nice to find a low-cost step-motor for it, too...
So you can see, that there's some small effort here, too, my friend.
1978 I was in Big Apple, Brooklyn, President Street listening to South American stations during our 3 week stay with my son. We had the opportunity to spend time in a Jamaican born family. I used to climb up to their roof to admire the lights of the skyscrapers on Manhattan. What a mighty view!

But also the so-called citizens'-band (about 27/28 Mc)
was filled with people talking and talking... One young woman was behaving like "Lolita", that is, she was speaking so softly and sweet like the fairy-singers of Homer's journeys.

But, thanks for your interest!

4914. Complementary Push-Pull Amplifiers

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-20 00:07:08 UTC
From: Chris Trask
Topic: 4914 Message: 4914

I just completed testing a pair of complementary push-pull circuits for use with active amplifiers using commonly available parts, and the results were pleasantly surprising. With a 2N2222 and a 2N2907 pair as the output devices, the OIP2 and OIP3 were measured (not estimated) as being +68.5dBm and +44.25dBm, respectively. The details of all this plus much more can be found at:

Very generous indeed from your part, Chris!

A stupid (?) idea came into my mind:
If there would raise interest among this group to get cheap these amplifiers, perhaps I could help by building (homebrewing) very neat and decent pieces? For 10 devices I only ask 1 for myself.
What is needed is construction drawings and boards for the components.
Because it is almost impossible to buy the parts here in Spain, there would be need to receive all parts preferably in one package from the U.S.A.

Perhaps someone could estimate a calculation for all costs for people to see, if it is worth going on?

Please note, that this is not a commercial, just a humble suggestion of a retired hobbyist!

Ofcource any other person may copy my idea for free. I'll be glad to pay for his/her work and both parts' and mailing costs. <For a small low cost package of "parts" there will not be any customs toll.>

Best regards to all, especially to Chris!

I have a PC board designed for both of those circuits as well as one for my earlier transformer-coupled design. I have a couple more PCBs to design before I send the whole lot out for fabrication. I also have PCBs designed for the ferrite loop antenna and my earlier QEX loop antenna, plus I want to do one for a shielded loop version that requires a slightly different tuning network.

Now that we can have IMD performance comparable to that of the design that uses the obsolete 2N5160, the next goal is to address the NF of this class of amplifiers. Not that NF is a serious issue at HF frequencies and below, but it is for VHF and above. I have a design in mind, but it will require using the transformer-coupled design due to the lack of a low-noise P-channel device. It's also going to get the PCB treatment, this time without going through the prototype stage as I really don't like doing Ivan board prototypes with these itsy-bitsy SMT transistors.

HI!
Interesting!
Amusing!
Perhaps you had a good laugh with both of us, my honourable members?

I didn't mean my suggestion to be a joke.
And I didn't want to earn any money with it, although receiving money isn't too bad a purpose for any person like me as my pension isn't too high at all.(By mentioning that I am not begging any money from anybody!)

After all, this is purely a hobby to me, not a media to gain any economic win.

If I wanted to help others by putting together something, that might be interesting and so obviously beneficial to their listening to radio, but not too easy for them to homebrew, would anyone really be capable of to have a heart to stand up against it?

After reading Chris's emails I may possibly have understood something badly wrong?

I didn't notice any copyrights, but maybe I was too hasty reading? If so, I must apologize again, and not offer any unwanted and perhaps strongly forbidden "help" another time?

I may have broken your rules again...

Regrettingly very deeply,

your Aimo.

Hi all,
Just I uploaded the 10m PCB Fractal Loop Antenna, model II at Photos section.
This second model was designed with more wide tracks than model I to strengthen the overall antenna. The size now is 197mm x 197mm, 7.756 inches.
For more details, please visit my web site at
http://www.m0wwa.co.uk/page/projects.html
Thank you.

Aimo - my friend. You need to loosen up and take life at a more leisurely and slower, more fun pace. I poked some fun because I like you and thought you might get a little laugh out of it. No offense was intended and I was not intending to dampen your enthusiasm for the project you proposed. But I do not want to play if it is not going to be fun.

It is very difficult to communicate humor in this rather strile email medium. Always think if me as a good friend, sitting with you in the local pub or bistro, and we are talking and joking about the same thing. The only difficulty with this situation for you is that by closing time I will have lost my wallet...! ;-)

Happy trails and good luck. /// Richards - K8JHR ///

I have found that it helps to make liberal use of "smilies" to show that you are joking or making a humourous remark, and they tend to be a universal language by themselves. This is especially true when joking with people whose first language is not English and they don't appreciate or comprehend the inflections of the language that we take as circumstance.

I'm at the point now where I'm contemplating having PC boards made for one or more of these amplifiers. Thus far I have the following three designs:

1. Transformer-coupled push-pull using a pair
of NE46134 or BFQ19 for the output stage.

2. Complementary push-pull output using J309
constant current source and BFQ19/BFQ149
output pair (Fig. 4 in the paper).

3. Complementary push-pull output using J309/J271
complementary input pair and BFQ19/BFQ149
output pair (Fig. 5 in the paper).

All three designs include ferrite beads for decoupling as well as a potentiometer for adjusting the bias current of the input stage for those who really feel a need to have something to adjust. The last two also include provision for adding a 1:1 wideband transformer for power supply decoupling so that the power can be sent up the cable.

I'm estimating that the cost of these boards will be in the vicinity of $US8 to $US10 with domestic USPS shipping. They will not have solder mask or silkscreen as that would almost double the cost of the boards in small quantities.

Aimo,
Sorry I have'nt got back sooner, a little crazy here. I know it must be tough having to work
with a indoor SW antenna. All though they may be challedging, they can perform just as good as outdoor ones. I prefer magnetic loops, they have low-noise, can be rotated for nulling and tuned with a capacitor. They can also be home-brewed keeping cost down. I've had excellent results with the one in the photo. Please consider the 1/2 inch (12.5mm) coiled copper pipe and a small capacitor like at:
http://www.mtmscientific.com/capacitor.html ---or--- http://
www.midnightscience.com/catalog5.html#part2. Aimo, because of your space resriction

why not instead of copper pipe use coax RG8 or RG58 it's fexible enough and can give a little in a tight space. Food for thought. Anyway I know President St well being a native of
Brooklyn, and lived on Dean St for a while not far away. In 1978 I also was in brooklyn and was 20 years old, enjoying all the SW and CB DX in cycle 11 one of the best yet.
Let me know and I'll try to help if I can.

Chris,
if the diodes are entitled to compensate variations of the temperature, is it worth for them to be in "physical contact" with the hottest transistors? I remember I did such a thing in a VHF SSB power amplifier I built years ago

For a power amplifier, yes as the temperatures will be elevated well
above ambient. For a small signal amplifier it's more a matter of sensing
the ambient temperature rather than that of the package, so close proximity
on the board is all that's really needed.

Thanks a lot for your nice email, Metrobase201!

I received today 2 RF amplifier kits from Australia. After I come back from assembly in Malaga, Fuengirola, I try to put together 1 of them to see, if I can pinpoint any interesting stations with it. I must bild the frame for a loop first and then put together the parts for an amplifier for AM, MW or SW. I wanted to test the other amplifier with the copper tube octangel loop I earlier made...
The kits came from www.oatleyelectronics.com .
Cost was Australian $ 22.50 each + pack post 17.39, all together in US $ 50.75.
Interesting to receive so many Australian stamps on the cover, 18 total! Most of them happened to be undamaged...
I'll email later, next week, if possible.
Best Regards,
Aimo

Thanks, Richards, for your consolation.
Surely you made a joke! I understood it like that, but unfortunately I just happened to see some possible sarcasm in it... Sorry for that, my friend. O.K.? No hard feelings anywhere. I admit, that I got overly enthusiastic, because such a noted professional person as Chris has started to give us so many good things, gifts, lately. I just wanted to show my eagerness to do at least something for our group's common benefit, because I see, that I have gained so much in my beloved hobby through you all.
I like your humor, Richards, so just go on making us laugh, why wouldn't you...

Aimo

Richards <jruing@...> wrote:

My wife and I are planning another trip to Europe - very likely Spain
and Portugal... and if possible, I will find you and we will enjoy
something cold that will make us both happy. Not sure when, exactly,
but I will try to put you on my trip itinerary. What should we drink
with our Tapas...? Hmmmm... More later as plans come together.

4933. Radiating element for small (less than a quarter wavelength), tuned loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-23 05:06:38 UTC
From: renopithicus
Topic: 4933 Message: 4933

I like small, tuned loop antennas. I regularly use one on 20 meters that has a radiating element made out of 1/4 inch diameter copper refrigeration tubing. This 1/4 inch tubing works well, and as a radiating element it is much, much more efficient than, say, 10 gauge copper wire.

Of course, an even larger diameter tubing would be more efficient still, but large diameter copper tubing is expensive and very heavy. So, I wonder if anyone has suggestions about what else I might try. I'm looking for something that's fat, but still lightweight and reasonably flexible.

Thanks,

Steve

4935. MW DXing Questions

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-23 00:28:12 UTC
From: Jeff T. Casey
Topic: 4935 Message: 4935

Hi gang,

I'm relatively new to mediumwave DXing and I have a couple of questions that I'm hoping someone here would be willing to answer. My apologies for the fact that my questions are not specifically about loop antennas -- I asked these questions on a DXing list, but received no response.

When a US AM station is listed as running a certain power level during "critical hours," when are the critical hours?

How does one find out what a US or Canadian AM station's day and night antenna radiation patterns look like? Is there a database of radiation patterns somewhere on the web?

Is there a term for the frustrating AM reception phenomenon whereby a signal fades for a few seconds such that speech becomes temporarily distorted to the point of unintelligibility, despite the signal still being strong enough that it seems it should be readable? Is the term for this "selective-fade distortion" or does that refer to something different? Does this phenomenon have something to do with multipath reception or is it caused by something else? Is the main purpose of synchronous detectors to reduce this annoying effect? If not, then what is the purpose of a synchronous detector and how useful are they?

Thanks very much & 73,
Jeff

From Wikipedia...
Critical Hours is that time from sunrise to two hours after sunrise, and from two hours before sunset until sunset, local time.

Day and Night pattern:
Go to http://www.radio-locator.com/, enter your stations call letters and hit go. If there is more than one station with that call letter, fox example Wxxx and Wxxx-FM, click the information link (little yellow box). In the technical information box is a link to the stations day time and night time coverage map. If you clink on the link following Transmitter Location, Google Maps will open showing where the transmitter is located. If you go to the satellite view you can often see the tower. It's real cool.

Hope this helps

Hi Jeff,

I'm not an expert ... but I do like DXing MW to a degree. To me MW dxing is done during the day. AM broadcast stations are generally licensed a differential power limit ... higher during the day than the night. There are some so called 'clear channels' where within which stations are licensed full power day and night ... up to the maximum. There may be some others who can elaborate on this. The differential power limit makes sense ... since once evening skip moves in all bets are off and a 500 watt station on the other side of the continent can come in with the same strength as the 5KW station located 20 miles away.

>How does one find out what a US or Canadian AM
>station's day and night antenna radiation patterns
>look like? Is there a database of radiation patterns
>somewhere on the web?

Again, station locations and licensed power is generally available ... however I am not aware of radiation patterns vs-a-vs licensing let alone publication. I would be interested to know if it is.

As I mentioned, to me MW dxing is a daytime occupation. However I am sure there are other serious MW dxers that listen at night. In which case dealing with QRM, cross modulation, fading, and all kinds of other interference is the object. For example if you are interested in verifying reception of particular stations at particular locations thousands of miles away you will need good directional antennas, an excellent receiver that can deal with multiple overload signals, and means of dealing with fading.. Some of the die hard dxers use various techniques to cancel qrm and fading using antenna phasing.

Your particular question about synchronous detection .... it helps .... however I use it primarily on weak SW broadcast reception. There may be some MW nighttime dxers who can say more.

4938. Re: MW DXing Questions

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-23 18:31:18 UTC
From: cank13cat
Topic: 4935 Message: 4938

Hi, Jeff,

An excellent resource is, believe it or not, the FCC database. Gummint websites don't always work well but the FCC database is an exception. Lots of info about stations, how much power they run day/night, etc. Even some info about Mexican stations that can be heard in the U.S.

http://www.fcc.gov/searchtools.html

Regarding broadcast patterns, some MW stations offer this info on their websites. WHO 1040 in Des Moines, for example, has some interesting info. It's often buried. Station managers and engineers are surprisingly receptive to questions and often welcome e-mail with questions about their operations and may direct you to where the technical info is buried on their websites.

You interpreted correctly the purpose of synchronous detection. Since DXing often involves direct and skywave propagation some interesting and quirky behavior can occur, which sync detectors can really help with.

For example, WBCQ transmits, nominally, on 5110 kHz in AM from afternoons through the night. Their transmitter is located in Maine. I'm in Texas. If I'm recalling correctly they're putting out 50,000 watts, but judging from the photos on their website the antenna is just a Yagi, no different from what many hams use. By the time that signal reaches me it's mostly fluttery skywave and centers around 5111.2 kHz. It's weak in normal AM mode, usable in USB and invisible in LSB. This is one signal where the sync detector on my Sony ICF-2010 shines. If I tune to 5111 kHz I get nothing; 5111.4, nuttin'; when I reach 5111.2 it pops into tune. The signal is never strong, but the sync detector grabs it and locks it in.

With strong signals the sync detector is useless and can even produce distortion. With deep fades it will continually lose lock. And, at least with the Sony (probably because the filters are too wide), the sync detector doesn't help isolate reception when two powerful stations are less than 10 kHz apart, which often occurs in the 49 meter SW band and some other popular broadcast bands. The reason it works so well with WBCQ is because while the signal is weak and off-frequency, it's relatively steady and there's no adjacent station.

So sometimes it's magic, sometimes it does nothing useful. I haven't found it to be particularly useful in isolating one station out of a crowd on the same frequency in the MW band. For example, there's a classical music station out of Kansas City on 1660 kHz. Pretty good signal to Texas, but there are at least two sports/talk stations on

the same freq. The sync detector can't help with this problem by
itself. It needs a highly direction antenna. (I'm hoping to squeeze
either a Wellbrook or Quantum loop into the budget this year.)

Hope this helps.

Day time is certainly when you should do comparative tests for sensitivity. Far, far too many people listen at night, hear a 50kW station 1500 miles away, and declare that receiver "X" is extremely sensitive. The reality is often that almost any receiver would be able to hear that powerhouse station under those conditions. During the day you have almost no skywave reception on MW. It's almost entirely groundwave. This makes for a level playing field and is when the differences in sensitivity between receivers should be most apparent.

However, most MW DXers would disagree with the contention that MW DXing is a day time activity. It depends to some extent on exactly how one defines "DX". Most serious DXers would agree it's not just a matter of distance. I think most would hang the definition on how unusual a reception is. I regularly hear the 50kW barn burners from New York, Chicago, and Detroit. I don't consider them DX even though they're all close to 1000 miles away. Yet, hearing a 500W station that's 200 miles away might well be considered DX, day time or night time.

I consider DX to be the catch that's not something that's regularly heard. It can occur day time or night time. This obviously depends on you being familiar with what's normal for your area, which takes a lot of time at the dials.

> ... since once evening skip moves in all bets are off and a 500 watt
> station on the other side of the continent can come in with the same
> strength as the 5KW station located 20 miles away.

If the 5kW station is on the other side of a huge mountain, maybe. It used to be a 500W signal could carry a very great distance at night. Today, though, there are so many stations and so much pollution of the RF spectrum that hearing a 500W station from the other side of the continent would be great cause for celebration.

If you want to do low power DX these days you need to move down to LW and listen for beacons. That's where, with the right equipment, you can hear a 25W transmitter 5000 miles away.

Well, my 20 meter loop consists of a 13 ft length of 1/4 inch copper tubing, fashioned into a circle and tuned with a butterfly capacitor. The copper tubing is great to work with because it is flexible but still stiff enough to hold the shape of a circle. The loop is fed with a short run of coax. Upon tuning the loop I'm just about always able to achieve a 1:1.2 or better SWR on 20 meters.

This is a modest little antenna, but it works. Today there was a Mississippi QSO party going on, and from my home in Brooklyn, NY I was getting 5 and 9 signal reports from these guys on the Gulf Coast. It was like shooting fish in a barrel. So, performance-wise it's about as good as it gets for a limited space antenna. It's not going to break through big pileups, but with patience it will get you some interesting contacts.

I hope this information is helpful.

Steve

Renopithicus,

First idea.

Instead of using one "fat" conductor, how about trying a number of parallel conductors arranged as a single fat conductor? Maybe use a piece of thick-but-flexible irrigation pipe as the support for the loop and glue the conductors to its outside. Wrap a bare wire around each end to join the conductors together (solder each connection). Imagine a line drawing of a toroid with an air gap. I'd try six single core conductors first.

I don't know how well it would work, what the multiple conductors would do to the inductance of the loop or any other parameters. I'm just putting this up as an "out there" idea.

Antenna modellers, do I crash and burn on this one or does it have validity?

Second idea.

Take the loop of irrigation pipe and wrap it with copper foil tape (sometimes on eBay under crafts). Solder the overlaps frequently so that it doesn't turn into a multi-turn toriod.

I don't know how they will work but logic tells me that the Q of these loops would be ginormous. This would make tuning precise, to say the least. I would recommend a vernier-driven tuning capacitor.

Ray,
vk5fyar

I agree with you. I am in a rather unique situation at my QTH ... in that there are now no local MW broadcast stations ... the last one on 580 KHZ changed over to FM .... All MW broad cast stations are south of me in Minn. and Wis. ... I have logged over 50 daytime stations ... the closest station is 150 miles away.

>DX, day time or night time.

I agree with you again. Nighttime MW DX is a different situation all together. For example if you want to log a MW broadcast station located on Tenerife you have no choice but to listen during the evening hours ... here the challenge is to deal with QRM and the other vagaries of the MW band when skip is in full swing hi hi.

>I consider DX to be the catch that's not something that's regularly heard.
>It can occur day time or night time. This obviously depends on you being
>familiar with what's normal for your area, which takes a lot of time at the
>dials.

What is real DX on the MW band is a matter of perspective and individual taste. Whether you log Tenerife at night, 1200 miles away ... or a 500

watt station on the Iron Range during the day, in Minn. 200 miles away ...
is a mute point. The skill and technique in either case is different ...
and in both cases a lot of fun.

Hi Ray,

Maybe I am missing something ... eg the theory behind 'Litz' wire ... but the surface of a wire is directly related to its circumference. Circumference is determined by the factor of 'Pi' or 3.14. What this says to me is that a wire with a diam. of '1' has a surface of '3.14' and a 'fat' wire with a diameter of 4 has a surface of 4 x 3.14 = 12.56. An if I create a 'mult-wire' of 4 wires each with a dia. of 1 ... the surface of this multi-wire will be 4 x 3.14 = 12.56 !! exactly the same as the fat wire.

Not all is lost!

The weight of the wire is directly related to the cross section of the wire. So the cross section of a 1" dia. wire is PI x R squared or 3.14 x .5 x .5 = .785 Four wires would weigh .785 x 4 = 3.14

The weight of a wire with 4 times the diameter would be 3.14 x 2 x2 = 12.56 !!! or 4 times as much !!!

So there you go, a wire antenna made of 4 separate strands would have 1/4 the weight of a single strand having the same surface area.

Steve,

Thanks for that but which butterfly cap do you use? Can I assume I could use another variable cap? Make one?

William W."Bill" McGraw
"Somewhere South of Chicago"
Greenville, MS 38701

Well, my 20 meter loop consists of a 13 ft length of 1/4 inch copper tubing, fashioned into a circle and tuned with a butterfly capacitor. The copper tubing is great to work with because it is flexible but still stiff enough to hold the shape of a circle. The loop is fed with a short run of coax. Upon tuning the loop I'm just about always able to achieve a 1:1.2 or better SWR on 20 meters.

This is a modest little antenna, but it works. Today there was a Mississippi QSO party going on, and from my home in Brooklyn, NY I was getting 5 and 9 signal reports from these guys on the Gulf Coast. It was like shooting fish in a barrel. So, performance-wise it's about as good as it gets for a limited space antenna. It's not going to break through big pileups, but with patience it will get you some interesting contacts.

I hope this information is helpful.

Steve

Is it the cross sectional area for resistance or actual external area of the wire for reception? If it is external area, then there is no advantage in smaller wire diameters. I can see where thin copper strips would give more area with less resistance (?). Set me straight as my physics is getting confused with geometry.

Bill,

Think in terms of skin-depth at the frequency range of interest then use multiple-parallel strands whose radius is at least 10% of the skin-depth (90% of the signal current flows in the 10% of cross-sectional area closest to the surface. The idea of multiple parallel strands is to increase the surface area while simultaneously decreasing the ratio of conductor resistance to radiation resistance.

I built a nice-working transmitting loop using a 2 inch wide strip of lightweight copper flashing. A 2 inch wide copper strip is about equal to 1 1/4 inch diameter tubing in surface area.

The skin depth at shortwave frequencies is only a few mils so copper flashing about 10 mils thick will work fine. The loop I built was supported by a wooden frame using pieces of white PVC pipe for insulators to support the copper strip. Someone could come up with a suitable plastic frame also.

With a little ingenuity someone could build a folding frame for easier storage or transport then fold it open using the flexible copper flashing strip. Would be great for portable use.

Hi Bill.

Cross sectional area is related to DC resistance. With AC the phenomena of
'Skin Effect' takes over and at HF and VHF the resistance is related to
surface area.

hi Bill,

Well the real story of why 'many' can be better than 'fat' re RF resistance starts with the fact there are 2 kinds of resistance in antennas. The normal concept of RF resistance (limited to the surface of the element due to skin effect) and radiation resistance which is a function of the design of the antenna. Power consumed in the more normal resistance of current flow is simply converted to heat while the power consumed by radiation resistance is converted to electromagnetic radiation (the function of the antenna!!).

If the design of the antenna is such that the radiation resistance is low then it becomes critical to make the RF resistance as low as possible since the ratio of the two gives the efficiency of the antenna. Small loop antennas are like this, having a low radiation resistance .... a circular surface seems to be the physical shape that gives maximum area and thus conductivity and thus maximum efficiency. The mass of the element material is not important in this scenario and thus the conductor can be hollow (like a tube) or flat and thin like foil. A tube has both and outside surface and an inside surface .... but then that is a different story/argument as to how that can relate to performance and so-called shielded antennas.

Getting back to one of the original questions, 'is it effective to use multiple wires instead of a single fat wire', the answer is yes .... but in context. A small transmitting loop with a low radiation resistance must be constructed of material like foil or tubing in order to have any useable efficiency ... eg as previously discussed. However in antenna or circuit design of a different nature such as mult-turn windings or longer antennas like full size loops or dipoles the construction material by definition is wire and not tubing. In these designs the bulk or mass is more important. Winding a coil with fat wire is difficult and it's size is a problem. Constructing a dipole or full size loop out of fat wire is

difficult because it is heavy and difficult to support.

It is possible to increase the surface area with multiple wires more efficiently (in relation to mass or weight or bulk) than using single fat wires. The reason is simple in that as you increase the diameter of wire the mass increases as the square while surface area increases in a linear fashion ... eg mass increases faster. So multiple wire antennas are sometimes used to maximize efficiency and special multiple insulated stranded wire (Litz wire) was invented to maximize efficiency of larger multi-turn inductors. But it must be mentioned that the increase in efficiency is not critical since the radiation resistance of long wire antennas like dipoles and full size loops is already quite high so marginal increase in RF conductivity is usually not worth the effort.

However, constructing a full size dipole out of tubing rather than wire can substantially improve performance but stops becoming practical from a physical point of view at about 20M.

You are missing something :) Take a typical wire, a seven strand wire, with 12AWG strands (O.K., not so typical :)So each strand has a radius of 0.5 mm, and a circumference of 3.14 mm. the seven strand bundle will have a radius of 1.5 mm, and a circumference of 9.44 mm. Since length and skin depth are constant, we can ignore these variables. The one thing you may not be aware of in this example is that the skin effect stops where the wires come into contact. so instead of having 7 times 3.14 mm, or 21.98 mm of skin, only 63% of the skin of the conductor is used. And none at all in the seventh conductor. So the actual skin of a seven strand conductor, as opposed to a solid conductor of the same diameter is 1.46 times the circumference of the solid. Which is better than the solid, which is why the RF resistance of a stranded conductor is lower than that of a solid conductor of the same diameter. Add more strands, and this number drops closer to the solid conductor as less and less of the circumference of the outer strands are conducting. And all the inner strands do not carry any current at all.

But what if in our example, the strands were insulated? Instead of only 63% of each outer six conductors carrying current, the entire 100% of each outer conductor carries current. And the seventh inner conductor which carried no current at all, will carry current too. So instead of 9.44 mm of surface for current conduction you have 22mm of surface area for conduction. So seven stranded, insulated, wire would have 2.33 times the conduction of a solid wire of the same diameter. That is a pretty big difference.

But we can do better when we consider that of each strand, only a small percentage of the area actually conducts. there are large swaths of area in each strand that do not conduct at all. Remembering that skin depth of conduction is not a function of the surface area of a wire, but rather frequency only, you can calculate the actual depth of conduction due to skin depth, then make the radius of the wire equal to the skin-depth. The result will be a much smaller wire, with a much smaller area of conduction, but the entire wire conducts, not just the outer skin. Apply a thin insulation to each strand, and bundle them together, and you end up with an equivalent wire that conducts as a function of area, rather than circumference, demonstrably a much larger value of conduction.

And that is what Litz wire does. And why Litz wire is rated by frequency. Lower frequencies require larger diameter strands. Higher frequencies require smaller diameter strands.

Mark.

No, I'm not missing this point. In order to increase surface area I agree each strand must be insulated from each other. This is in fact how 'Litz' wire is made.

Jim

Thanks Mark,

Very good explication of how and why Litz wire works.

Along that line of thinking, bandwidth is a function of element diameter. The larger the diameter, the broader the bandwidth. Since few can afford 6" copper pipe to construct an antenna an alternative is to run wire with "X" spreaders to give an effective larger diameter element.

Back in the 1920's it was common practice to run parallel wires which had the same effect. Since the wire spacing is so small compared to the wavelength the RF really does not see the space between the wires.

Using the above methods, and the room to run a nice length antenna cheap electric fence wire can be used quite effectively. Steel MIG welding wire is copper plated and can be used too.

If you are building one of the antennas that requires a terminating resistor you might consider using stainless steel wire. SS wire is a rather poor conductor compared to copper and depending on the length needed the SS wire might have the needed resistance built in eliminating the need for the resistor.

exactly
> the same as the fat wire.

You are going about it the wrong way.

Take a wire of diameter 1. Circumference is therefore 3.14.

Now replace it with 4 wires that fit in the same circular area. Each wire has a diameter of 1/2, -not- 1/4. So 4 wires, 1/2 x 3.14, is a total surface area that is 2x the original.

7 strands is more common, one central with 6 around it. But that isn't 1/6 or 1/7th the diameter, it is 1/3. So 7 wires x 1/3 diameter x 3.14 is 2 and 1/3 the surface area.

Think about it simplistically: take a wire, split it down the middle line and insulate from each other. Is the surface area the same?

Your math for the weight doesn't work out, either. The split wire above, does it weigh less than unsplit wire?

Steve Greenfield

Hi Steve,

We are both right to a degree .... the perspective has a way of channeling one's thinking. But first lets agree on some basic facts:

-In a solid wire diameter (x) the area of the cross section is directly related to the mass or weight and the DC conductivity of the wire.
-In a solid wire diameter (x) the circumference of the wire is directly related to the surface area of the wire which in turn is directly related to the RF conductivity of the wire.
-If you increase the diameter of this solid wire the surface area and thus the RF conductivity will increase in direct proportion while the cross

section and thus the mass and DC conductivity will increases as the square.

Now lets look at stranding the wire. You are right, 7 is a magic number. Seven circles can be put together so they will all touch ... 1 in the middle and 6 around. Lets go from your perspective and start with a solid wire with a diameter of 3 (you mention 3 as the number that relates the diameters of individual strands to overall wire diameter with 7 strands). If you strand this wire and keep the same overall diameter you could use 7 strands each with a diameter of 1. Now lets compare the effect of this process on the mass and surface area of this new stranded wire.

The solid wire would have a cross section of 7.1 and a circumference of 9.4 ... while the stranded wire would have a cross section of 5.5 and a circumference of 22. Thus, the process of stranding a wire (keeping the overall diameter the same) has reduced the mass, DC conductivity, and strength by 23% and at the same time has increased the surface area and thus RF conductivity by 230%. This is the point you were making. (the added RF conductivity assumes the strands are insulated one from the other).

Now one of the points I was making was when you increase the size of the wire the mass increases as the square while the surface only increases in direct proportion (true whether the wire is solid or stranded). So now lets take the same 7 strand wire and double the size ... e.g. overall diameter is now 6 and each strand has a diameter of 2. Sure enough, the mass is now 22 up a factor of 4 from 5.5, and the circumference/surface area is now 44 up from 22 a factor of 2 (which is directly proportional to the overall diameter increase).

This is what Herr Litz discovered many years ago. Now the reason stranded copper wire is often used for hanging wire antennas (e.g. your 80m dipole) can't be to increase surface area and thus RF conductivity ... calculating the outside surface area is beyond me ... however i assume it must be very close to that of a solid wire of the same diameter. The reason must be mechanical ... in that stranded wire seems to handle various stresses better than solid equivalents.

I enjoyed your posting .... it did a lot to clarify my thinking ... hi hi

Jim

What you are talking about is a cage antenna (cause it looks like a cage, don't you know :)

A wire consists of several electrical components. These are resistance, inductance, and capacitance. The resistance is a bit tricky, because of skin effect, which makes it have a higher resistance than at DC. The Inductance and capacitance are a function of length and area of the wire. At a given frequency, the inductance and capacitance equal, and cancel each other out. this is the resonate frequency. The bandwidth of this is a function of the RF resistance, as well as the impedance of the inductance and capacitance. This is called Q.

Now here is where the cage antennas come in. If you increase the diameter of the wire, you increase its capacitance per unit length. This means less inductance is needed to bring it into resonance, and the total length decreases. So you get a shorter, but thicker antenna.

And since gaps of 1/20th wavelength are for all intents and purposes invisible to the RF energy, the conductor need not be solid. you can run wires a foot or two apart, and it will appear solid to the RF energy.

But everything has a cost. In this case, the higher capacitance per unit length means you have a lower Q. This translates to less gain than a normal dipole. On the other hand, lower Q means that the impedance of the antenna feed point does not change as drastically as you tune off the frequency, giving you a wider bandwidth.

For receiving, the lower gain is not that critical, especially at HF where the atmospheric noise is quite high. You can always make the gain up using a preamp, On the other hand, the 'wire' has to get quite large in diameter before you get an appreciable decrease in length or increase in bandwidth. There is a program on S-Meter that will give you good ballpark values for a cage antenna. It is fun to experiment.

So why use a Cage Antenna. They are more for nitch applications. Say you need wider bandwidth than you would normally have for a dipole, but not very wide. A good example is 500-700 kHz at 6 MHz. You could use a Terminated antenna, but the Terminated antenna works by having the termination resistor 'eat' some of the reflected power. This helps stabilize the input impedance of the antenna over a wide bandwidth, but it is a less efficient radiator (or receptor) because the power that the termination converts to heat cannot be radiated. Another case of no free lunch.

But cage dipoles do look neat.

4962. Another capacitor question for the group

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-26 03:01:19 UTC
From: metrobase201
Topic: 4962 Message: 4962

My shortwave copper loop (3 feet circumference_see photo section) has a 365pf cap which resonanates from 4500khz to 15000khz. I've added a second cap w/switch and when switched on goes down to about 2350khz. That fine and I want that. But my question is to go up to say 22000khz "What type of capacitor fixed or variable can I either add in parallel and/or switched in to get up that high.

Thank you group in advance.
-MetroBase

4963. Re: [loopantennas] Another capacitor question for the group

Topic: 4962 Message: 4963

Metrobase,

The loop will exhibit a natural resonance and it will be difficult to get the loop to resonate above that frequency. I can't say what the natural frequency of the loop is. You need to disconnect the capacitor and test the loop. If the loop resonates naturally above your top desired frequency then we can do things.

Assume that the loop DOES resonate above 22MHz:

Resonance occurs when the reactance of the capacitor and the reactance of the inductor are the same.

You do not specify the low value for your capacitor and so I will have to work from the fully meshed value which you have quoted as 365pf. You say that the loop resonates at 4.5Mhz when the cap is fully meshed.

Finding L:
Our formula is Fo = 1 / 2II SQR(LC)
Transpose the formula for L (the inductance of the loop).
L= 1/((F2II)squared)C (F = 4,500,000)
L=3.4uH (or thereabouts)

To get the low value of the capacitor:
Our formula is Fo = 1 / 2II SQR(LC)
Transpose for C (the low value of the capacitor)
C = 1/((F2II)squared)L (F = 15,000,000)
C=33pF

So we have a 3.4uH inductor resonating with a 33-365pF capacitor.

The desired resonant frequency is 22,000,000Hz

Our formula (once again) is Fo =1/2II SQR(LC)
Transpose for C again
C= 1/((F2II)squared)L (F =22,000,000)
C = 15.4pF.

So to tune your loop to 22MHz, you need to get the low value of your tuning assembly to 15.4pF. The lowest value of your tuning capacitor is 33pF and so you need to insert a series capacitor.

The formula for capacitors in series is 1/Ct = 1/C1+1/C2....1/Cn
Transpose for C2
1/C2=1/Ct-1/C1
=28.8pF

The nearest preferred value of capacitors is 27pF.

To tune to 22MHz (natural resonance permitting) you need to insert a 27pF capacitor in series with your tuning capacitor. When the tuning capacitor is fully meshed the effective capacitance is 25.1pF. When fully unmeshed the effective capacitance is 14.85pF. This will give a tuning range (series capacitor in circuit) of 17.2MHz to 22.4Mhz (give or take a coupla KHz).

That's the maths of the theory. BUT(a big but) there are always stray capacitances. Try the 27pF and test. It is unlikely that the loop will resonate too high for you with the 27pF. If it still resonates too low, drop the 27 down. 10pf parallel 15pF makes 25pF. Two 12pF's parallel makes 24pF. 10pF parallel 12pF makes 22pF. Two 10's make 20.

Or get a trimmer capacitor say 10-30pF and adjust it.

Waddayarekon guys? Is my maths right?

Hi Jim, there is not such Herr Litz.

Litz is a short for Litzendraht that means "stranded" in german.
So "litzendraht wire = stranded wire"

But your explanation was very interesting. Thanks.
Jose

4965. AM & SHORTWAVE LOOP

From: Jim Miller
Topic: 4966 Message: 4966

For those of you that have used refrigerator grade copper tubing, what sizes have seemed to support themselves if the diameter is bridged vertically by something substantial? Will 1/4" be enough or is larger required to keep it from drooping into a pear shape? HomeDepot has sizes up to 5/8" OD but I'd like to use the smallest possible.

I'm looking at making a loop out of 2" copper strap, either 0.011" or 0.022" thick, and I know that won't support itself. Circumference will be 5 meters.

I was thinking of making an loop out of smallish copper tubing for support and then attach the copper strap to the outside of that with periodic solder joints. The copper strap will be the primary RF conductor. The copper tubing would just be there to support the strapping without causing dissimilar metal problems. Soldering makes for easy attachment. I was thinking of some polycarbonate tubing as the vertical diametrical support. Haven't figured out much beyond that.

I'm trying to make this thing look "pretty and sculptural" rather than my usual "ugly but works" approach since it will likely be a backyard installation, hence I'm trying to minimize the amount of elevated PVC. I'll likely have PVC in some places down below where it won't be noticed.

The less it looks like an antenna the more likely it is to be accepted...

tnx

Midnight Science sells parts for crystal radios, and carries 365pF
single and dual gang tuning caps.

http://www.midnightscience.com/

You might also watch thrift stores for old radios. The old big AM
portable radios often use air variables, if they are old enough. Very
old clock-radios and table radios used air variables, if they are old
enough. I've gotten a lot of air variable tuning capacitors this way.

What about making an octagon out of thin walled PVC pipe and
wrapping the copper foil around it is a ling spiral?

Or, if you want to make it all out of copper, an octagon
made of type M, Thin wall rigid copper pipe) soldered into
45 degree elbows.
http://www.acehardware.com/sm-working-with-copper-pipe--bg-1280921.html

One inch type M pipe (actual outside diameter 1.125") is not
a lot more expensive per foot that the soft (very pure)
refrigeration tubing of considerably smaller diameter and is
much more self supporting.

Hi,

In order to bring the circuit back into resonance at this higher frequency you will have to lower the inductive reactance of the coil to bring it back into the range of the capacitive reactance of your capacitor. In order to lower the inductive reactance you need to lower the inductance .... in other words you need to make the loop smaller. Capacitors are funny things ... unlike inductors the capacitive reactance moves in the opposite direction to capacitance. Pretty hard to get more capacitive reactance from a capacitor already at minimum.

If you Google the net you will find a number of mail order suppliers ....
but I have used old radios as a source ... check out garage sales etc ...
there are always some old radios that can be had for a song and they
usually have some excellent variable capacitors you can use for both kinds
of loop antennas. The only problem I find is I am usually torn between
scrounging parts and restoring the old radio hi hi.

Hi Jim,

Interesting construction project .... first, is the copper strap solid or braided? The reason I ask is that braid is easily distorted which has a negative effect on RF conductivity. For my following comments I will assume it is solid copper strap. A 5 meter circumference is pretty big ... not too big .... but pretty big hi hi. .... 16.25 ft or just over 5 ft in diameter. I have built a number of self supporting loops from 5/16" copper tubing ... to about 3 to 3.5' in diameter. They were self supporting from the base. If you split it at the top ... with some tuning capacitor ... then it won't be self supporting .... you will need that center support at least.

Interesting concept of spot soldering the flat copper strap to the outside of the tubing. I think that would provide not only added RF conductivity but rigidity to the loop. It is a construction trick used in the housing

industry when manufacturing floor joists. Even then, I am not sure if 5/16" copper tubing would self support at 5' diam. (by the way I acquired a large role of 5/16 copper tubing years ago and use if for a lot of projects)

Your project should have something between 5/16" and the 5/8" you mentioned. However, larger is always better (from a performance point of view).

If you can build it, feed it, and tune it without slitting the top you could make it free standing and hang a nice wind chime in the center. No one would be the wiser.

Jim,
I've used 1/4" refrigerator tubing for my 1m diameter and 2m diameter loops, but it needs some support even for small sizes such as that. 1/2" refrigerator tubing works well for the smaller loops, but still needs a support going up the middle. Hard 1/2" and 3/4" tubing could be self-supporting, but you would have to devise some method of bending it, such as a pretty hefty form made from plywood much like a conduit bender. Even so, you would still need some sort of PVC support going up the middle.

at the risk of talking to myself...

i just figured out that if the smallest copper line is insufficient i can just run a length or two of electricians snake (spring steel) inside to make it hold it's shape.

it won't see any rf since it will be sealed inside the copper.

sorta like home brew copper clad steel. ;-)

i like cheap solutions!

I've built a lot of different type and different size of receiving loops. They usually work on all bands, the same as my receivers, from 153 Kc/s to 30 Mc/s.

My humble opinion after testing them is as follows: What ever you can use successfully, depends on your personal wishes!

Any size antenna, from a 1" object of most metals to miles or kilometers of any metal wire or tube (or even water) will give you some radio stations, if you are using some kind of an antenna tuning unit, an antenna amplifier or an amplified preselector. But if you could use the most sensitive receiver, even your body could be an almost perfect antenna! Earth will be a very good antenna as well. The Scandinavian DX-contest was once one connecting the antenna connection to the warming element of a house. (Archives show, that the Scandinavian DXers are amongst the top of this planet's rare-DX-hunters.)

But ofcource, if you want to discriminate disturbing transmissions from a different direction than where your favourite transmitters exist, then you should preferably have super-directive antennas in your possession, 1 mile or more to one direction and 15 other about as long wires towards other possible directions. Or build a huge turnable beam (Yagi), but it should be very heavy and gigantic of its measures (and very expencive, too!).

Those small loops surely are just very light substitudes, when we consider, what really is effective! But most of us must be relatively satisfied with "substitudes", right? So the smart salespeople are receiving their living (and more) offering their products to us, who only are able to use hundreds instead of tens of thousands in any main currencies to buy their equipment...

Just the other day I happened to read an opinion of making better antennas at home, than those offered by the commercially thinking people...

So, let us study and try to make our best to homebrew one or two of our own!

It is nice to be able to do it with own hands with the help of such nice persons in this group, who make their inventions known to us, free!

Best regards from your friend Aimo.

I made an "octagon" of 1/2" copper tube, 130cm diameter (4,3') or 41,4' (408cm) of length. For supporting frame I have a "cross" of 7/8' wood.

Time will tell, if it's going to work as well as I was expecting?

I must go out and test it and add a proper amplifier, if needed and ofcource an A.T.U.

Now it's hanging on my window waiting for future final tests...

But it is working as that very well, but no real DX, yet.

Best regards from Aimo.

Jim Miller <jim@...> wrote:
For those of you that have used refrigerator grade copper tubing, what sizes have seemed to support themselves if the diameter is bridged vertically by something substantial? Will 1/4" be enough or is larger required to keep it from drooping into a pear shape? HomeDepot has sizes up to 5/8" OD but I'd like to use the smallest possible.

I'm looking at making a loop out of 2" copper strap, either 0.011" or 0.022" thick, and I know that won't support itself. Circumference will be 5 meters.

I was thinking of making an loop out of smallish copper tubing for support and then attach the copper strap to the outside of that with periodic solder joints. The copper strap will be the primary RF conductor. The copper tubing would just be there to support the strapping without causing dissimilar metal problems. Soldering makes for easy attachment. I was thinking of some polycarbonate tubing as the vertical diametrical support. Haven't figured out much beyond that.

I'm trying to make this thing look "pretty and sculptural" rather than my usual "ugly but works" approach since it will likely be a backyard installation, hence I'm trying to minimize the amount of elevated PVC. I'll likely have PVC in some places down below where it won't be noticed.

The less it looks like an antenna the more likely it is to be accepted...

That's true for tuned loops, however a broadband loop will work fine over a much wider frequency range. Witness the Wellbrook loops. Of course, if you make a broad band loop you'll need a decent hopefully balanced loop preamp, because the BB loops aren't resonant and so don't provide as much signal as a tuned loop... But you don't have to tune them!

In my experience with my Wellbrook ALS-100M larger aperture loop, I found it produced a signal as strong as my 75 foot random wire antenna. No loss of signal strength - and it was as quiet (or as noisy, as you will) as the random wire.

I took my random wire down to make room for a 160/80 meter sloper transmitting antenna. I often use my Wellbrook ALS-100M loop as a receiving antenna when transmitting. I listen on the one, transmit on the other. Tuning the random wire up for 160 meters sucked, so this arrangement works much better for me. I still have a decent receiving antenna and I now have a much better transmitting antenna for the top bands. I do not miss the random wire, which should have produced a stronger, quieter signal.

My Wellbrook loop uses a larger loop, one you make yourself, out of wire - and mine is square and 20 feet on a side, fed at the bottom for horizontal polarization. Feed it on the side and it favors vertical polarization. This is much larger than the one meter diameter aluminum loops they sell. I think this larger loop is what accounts for the strong signal response.

I have no complaint that it is broad banded. I just tune around the bands - no fussing with it.

This will be for transmitting as well as receiving for 20, 30 and 40M.

I could always go for an octagon but I wanted to try something different with no solder joints. The 2" solid copper strap gives a radiating surface equivalent to 1.25" diameter tubing. This isn't really a novel approach just some tweaks on good work done by others.

Both DX Engineering and TheWireMan have solid copper strapping. I'll probably go with the material from TheWireman since it is twice the thickness and therefore more rugged than the 0.011 material.

I know I'll need a vertical central support. With my windy QTH I'm probably going to do four diamond guys with the spreaders just below the loop terminating at the top below the capacitor housing on the central support and equidistant on the loop support pole below; probably about 4ft in each case. That should keep the torques of windload from ripping the loop from the support post.

I expect to support the loop atop an 8ft metal post which will turn with the loop. The spreaders will be at 45degrees to the plane of the loop.

Still working on the cap details and its housing.

Ray, thank you for the math and theory. As always you guys are a big help. Seem a bit complicated but let me see if I understand in laymans terms. The lower value of the capacitor 33pF does not let or is'nt low enough to get that high when fully inmeshed. In other words won't resonate from 15khz~22khz. In order too I have to lower the pf I need to insert a series capacitor of 27pF to the variable capacitor in series. And thats a big maybe. Hope I'm correct. You have pointed me in the right direction and I'll experiment. Tell what type of capacitors, ceramic or other kind???
Thanks again hoping to hear from you soon.

4983. Behavior of feed line

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-02-27 18:28:30 UTC
From: Jim Dunstan
Topic: 4983 Message: 4983

I need some confirmation on an assumption Re: 1/2 wavelengths of feed line. I assume if I connect a resistive load (50 ohms) across the end of a feed line (300 ohm twin lead) and cut it to a 1/2 wave length at 14.07 mhz for example (taking into account velocity factor) that the impedance I would measure on the other end would be 50 ohms .... a reflection of the load. I could connect any length of 50 ohm coax after that point ... using a 1:1 balun at the connection point.

Thanks,

Jim, VE3CI

Hmmm... You could possibly bend 5/8" copper pipe with a 1/2" EMT
bending tool.

Hi,

I don't see why not. I have seen and used Quad antennas with 2 to 5 driven loops with the same number of reflector loops. the driven loops were all driven by the same feed line. Each loop is 1 wave length. These are vertically oriented loops ... I don't see why the same principle wouldn't hold for a horizontal version. However, I would see some mechanical problems in suspending loops of such different size as 80m and 20m.

That is correct, with certain qualifications.

It is exactly correct for ideal lossless feedline. When you add losses, the impedance seen looking into the line tends to move towards the feedline's characteristic impedance (300 ohms), which gets worse the longer the line is and the more lossy it is. In the limit as you concatenate together infinitely many of these 1/2 wavelength (non-ideal, lossy) sections together, the impedance seen looking into the line approaches the line's Zo (300 ohms), regardless of what load resistor you have on the other end.

Your technique of using a 1/2 wavelength line of the "wrong" impedance, is indeed sometimes used.

Theoretically it only holds for some bandwidth around the frequency where the line is electrically 1/2 wavelength long (taking into account the velocity factor, as you note), and the impedance would deviate from what you want as you diverge from that frequency. But with only one 1/2 wavelength section, the bandwidth of this impedance transformation is fairly broad.

Twinlead's losses increase somewhat when it gets wet.

Has anyone tried filling the copper tube with sand or salt to bend
without kinking?

Hi Andy,

Your information is really interesting ... eg feed line loss driving the
feed impedance closer to the inherent impedance of the feed line (in this
case 300 ohm). In my case I have a mechanical reason for inserting a
single 1/2 wave length of twin lead in the feed line. I don't expect to
realize significant loss at 14 mhz from a single half wave (32') of good
quality twin lead.

Thanks

Jim, VE3CI

Oooooh!! I hadn't thought of that. Together with a plywood form to get the curvature correct, that may be a simple, cost-effective solution.

From: RICHARD JURKOWSKI
Topic: 4992 Message: 4992

The tube MAY kink if the bend is too sharp.
When I raced model boats we would heat the copper
tube with a bernzamatic torch until red hot then
drop it into a bucket of water to cool.The part
that was heated will be softer and bend easily
without kinking.If desired it can be heated again
and immersed into OIL to harden it up.
Good Luck,
Rich WB2WGX

When I work on AC I use a spring for each side of copper
use that will bend copper and not kink. look at the hardware
and see if they still have thye spring..

Use a tubing bender!

It's a long spring type tool that goes over the full length of the bend, it keeps the tubing from going out of round!
Lowe's, home depot etc...

An alternative method for bending tubes is as follows (I have never done it, but I remember from the text books):

Close one end of the tube by soldering an end piece to it.
Fill the tube completely with fine, dry sand.
Compact the sand as much as possible, make sure the tube remains completely filled.
Close the remaining end of the tube in the same manner.
Now the tube can be bent, it will not kink in sharp bends.

I remember to have seen a movie when I was a small boy about the fabrication of trombones, instead of sand oil was used. The closure of the ends of the tube was not done by soldering I suspect, but I can't recall those details.

Hi Cris and Cor, Packing sand into the tubing and then bending around a mandrel or form works very well. Our company manufactures transmitters and antenna products which involves bending tubing from 3/8 inch to as much as 3 inches or more. We flatten one end of the tubing as a seal, and pour sand into the tubing, while tamping down the tube. (For a tube that is 20 feet long, that means someone up on the roof pouring in the sand.) We have a device which bumps up the tube to ensure that the sand is packed tight. Once the tube is filled, the other end is flattened, and the tube is then rolled around the mandrel, flattened, or formed to create the coil. The hard part can sometimes be removing the sand.
Best regards,
Paul

I seem to recall that the method of filling the tubing with sand was seen in the movie "Flight of the Phoenix" (the original, not the remake) where the model airplane designer was distilling water from barrels of antifreeze, or something like that.

5000. K256 Active Loop Antenna Kit

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-03-02 22:33:38 UTC
From: aimo ruoho
Topic: 5000 Message: 5000

I built one, (I purchased 2 of them)...
I am still testing it, but I have to be more thorough to be able to see, how it works on separate bands. It gives some signal between LW and SW bands, especially on the tropical bands. On lower bands it is directional, but I think, that I should omit all metal screws and the steel frame tube for moving it and change them to plastic or nylon or wood. My window has a metal grating (probably to prevent robbery, as is usual in Spain!), which may not be too favourable for directive antennas. So I should test this cross-formed loop outside the house on my upper roof, I suppose, to see the total effect of it?
All in all, this loop seems to work, which is not always the absolute case, when you buy a new kit and try to understand, how to manage in building it!

Best regards and opinions from your part, please!
Aimo

Hard copper tends to kink or at the very least oval out quite a bit (I doubt that would harm reception though) ... You can buy springs for bending hard copper without kinking it, that's that I did to make a quadrafilar helix for weathers sats ... It's a lot of work still to bend it without kinking

I used to use a similar technique for bending 2" PVC conduit ... I had
a heater I called the Easy Bake Oven (I used to cook sandwiches in it
for lunch) and a set of plugs for 1" - 2" PVC and you put the plugs
in, place the section you want to bend in the oven until it is soft
and then bend a 90 or whatever angle(s) you need and the plugs hold
the air in and that keeps the PVC from collapsing when you bend it
.... That saved having to buy a 90 and 2 couplings as well as made for
a smoother pull as you don't have the joints to hang up on when you
pull your wire which is critical when you are pulling 3 wires large
enought to carry 100-100 amps of current ....

5003. Baseline loop testing?

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-03-03 00:41:52 UTC
From: Jim Miller
Topic: 5003 Message: 5003

As I'm scheming the implementation of my ultimate loop I thought it would be smart to think about testing so as to know when I've screwed something up. ;-)

Since my loop is nearly 1/4 wave at 20M I thought that before hooking up any fancy capacitor I'd try just overlapping the loop ends a bit to achieve resonance. With just air for dielectric and no solder joints or mechanical complexity this should represent "as good as it gets."

Since the loop will be made of 2" copper strap with a copper tube stiffening rib I thought I'd start by suspending the loop in free air about 8ft off the ground and having the suspension line pass through to the bottom to support the whole thing to maintain its circular shape. I'll need to make a matching loop and that will get suspended in the same way. Obviously this rube goldberg mess will need to be tested on a calm day.

I've got an AA908 to measure the impedence with but I'm not too confident in its ability at this frequency. If can get to 2:1 SWR I can use a few feet RG-8X to get far enough away and there shouldn't be too much loss to confuse the measurements. As long as I can get the loop to resonate somewhere in the CW portion of 20M I should be able to evaluate how good it is by measuring the Q.

I can use my test generator to produce a sweepable test signal and measure the -3db points. I thought I might use my PIC powermeter to measure the signal strength and drive the test generator into an open 50ohm load several feet away. Any other ideas?

Once I'm satisfied this measurement is repeatable it should give me something to compare my various capacitor implementations against as I attempt to make caps which can allow the loop to tune 20, 30 and 40M. It will also be interesting to see how the Q compares to the values estimated for this design by the various loop design programs.

I'll also repeat the measurements with the overlapped-end approach with a PVC central support in place and again once it is mounted on something. I'm currently planning to mount it on a metal post with a saddle and a clamp with a base height of 8ft.

I'm going to order the copper strap from Wireman tomorrow and get the 1/4" copper tube from HD. Still need to design a plywood fixture to seam the two together.

Comments and recommendations welcomed.

tnx
jim ab3cv

There are some low melting bismuth alloys that can be used to fill tubing to keep it from kinking or flattening. One such alloy melts at 117° F, but is rather expensive. Another alloy melts at 160° F and is much cheaper. Since both melt below the boiling point of water the tubing would never be heated anywhere near the point of annealing it when filling or removing the alloy from the tubing.

Trumpet and trombone makers use a soap solution for making the bends needed in brass tubing. The tubing is filled then frozen with this solution inside the tubing. I do not know what solution they are using, but it would be worth looking into.

Filling the tube with about any liquid and tightly sealing the ends ought to work as long as you work the tubing at room temperature. The hydraulic pressure inside the tube would prevent it from collapsing.

Trying to tightly pack sand in a long tube would seem to be rather difficult if not impossible.

Sources for low melting alloys:

5006. Ideas for a test loop?

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-03-03 15:35:24 UTC
From: Ken
Topic: 5006 Message: 5006

I am looking at buying a Wellbrook ALA 330S but before sending my hard earned cash across the world I would like an idea of how a loop would work in my location. I am thinking of building a test loop and would like some input on where to start.

Some info...I have no interest in the AM band...my main interest are utilities in the 4mhz to 21mhz range....I have 100,000 volt power lines about 200-300 metres away. It's the noise generated by these power lines in rainy or foggy weather I am hoping the loop will help with. I do not have the room on my property to build a large wire loop. This will be Receive only.

Am I correct in assuming loops are just like a dipole in that the larger the diameter single turn copper loop the easier it will be to resonate between 4-21 mhz?

The tuning capacitor for a HF loop is Higher in capacitance or Lower than a loop used for the AM band?

Thanks for any ideas and help you can give me.

Ken

Hello Ken ---

A couple of things spring to mind, although not really a comprehensive answer to your questions. Initially, I think building a test loop will only prove whether or not your test loop works well or not, and will not have any transferable relevance to the proposed Welbrook loop. Unless your design is very similar to the Wellbrook loop, it will not serve as a valid comparison.

Having a Wellbrook ALA-100M loop, myself, I believe the Wellbrook loop you mention will, pick up about as much noise as a random wire antenna fed by coaxial cable and a 9:1 balun/transformer. If you have significant RFI/EMI from the power lines down the block, and you pick that up on this type of random wire antenna, you will pick up about as much of the same hash on the loop. I know, in theory, such loops are supposed to focus on the magnetic portion of the signal, and less upon the electrical portion of the signal (which is supposed to be where the noise primarily resides,) but I don't think the loop you inquire about will sufficiently disregard the power line noise, assuming there is power line noise, to warrant the purchase.

Do you know that you are picking up noise from those power lines? They might be far enough away not to be causing your problem.

I suppose you are correct that the size of the loop relates to its frequency, somewhat loosely analogous to the way the length of a dipole antenna relates to its resonant frequency. but only in a very loose, generalized manner. Yes, size matters, but so do many other factors. You can use various loop calculation formulas and calculators you find on various websites and in antenna handbooks, to determine the optimum size for your loop. The size, type, and characteristics of the material used will impact those formulas.

Just MY take.... Happy trails and 73. ---- Richards - K8JHR ----

Ken,

Dealing with your queries in reverse order.

A tuning capacitor can just as well tune HF frequencies as it can MF frequencies. A loop antenna (any antenna actually) is at its best when it is resonant. Resonance is determined by both the capacitance of the capacitor and the inductance of the antenna.

This means that if you have an antenna with an inductance of x microhenries and it resonates at 1MHz with a capacitor, an antenna of .1x microhenries will resonate at 3.3MHz with the same capacitor.

The formula for resonance is 1 / 2pi SQR(LC). L=henries C=farads Frequency in Hertz.

Loop antennae (all antennae) have a natural resonance. The bigger the loop the lower the natural resonant frequency because the natural inductance of the loop is larger. Also antennae have inbuilt capacitance. Various factors affect this such as the size, shape, number of turns and proximity of metal. The natural inductance and natural capacitance give the loop its natural resonant frequency. You can't resonate a loop above its natural resonant frequency because you cannot have a minus capacitance.

To get the best performance from a loop over a band you need to make the loop as large as possible so that its natural resonance is the top frequency you want. You can then resonate it down with the variable capacitor.

Getting a loop antenna to swing between 4 and 21MHz is a fair ask and the performance at the bottom frequencies would be down a bit. I would recommend making two loops - one with a natural resonance at 21MHz and another with a natural resonance at about 10MHz. This will give you a fairly constant performance as you tune across the bands. Small plastic-dielectric variable capacitors are about the cost of a cappucino and will do your job nicely.

Don't use iron wire for your loop - its Q is unsatisfactory.

I am only 20 metres from HT power lines and I find that the RFI from them is worse at lower frequencies. To test if a loop will be staisfactory for you, just build a low frequency 4-10MHz test loop - it will tell you what you want to know.

Goto www.dxzone.com and follow the links to loop antennae for lots of good info. You will also find links to loop antenna calculators to help you

get it right easily.

Ray,

First off thank you to both you Richards and to Ray for your replies!
You both gave me lots to think about.

As for the powerline noise, yes it is from the lines but only when it
rains and/or is foggy. I think the moisture on the surface of the
powerline wires conducts for a split second. If you stand under them
(there is a dog walking trail there) you can hear them "hissing" in
the rain or fog.

I think I will build a 10mhz loop just to see if it rejects even a
part of the noise.

I have some 0 gauge copper ground wire which is about 6mm/.25 inch.
Would that work? It's quite stiff and about 5-7 strand.

Ken

Hi Ken,

The Wellbrook antenna looks to be a small loop with a preamplifier.
Many of your questions would be answered by obtaining some useful
information with a small loop calculating program. I suggest
loopcalc.exe, which you may download here:
http://www.qrz.com/download/antennas/loopcalc.zip

You are correct that a loop antenna tends to reject the electric
component of electromagnetic radiation, however this works best before
the electric and magnetic fields merge into electromagnetic radiation
ie radio waves. So the closer to the source, the better the ability
for a loop to reject the noise.

Another use for a small loop to reduce noise is to rotate the loop
such that the noise source is in the null of the figure 8 loop
pattern. For a small loop this occurs when the plane of the loop is
perpendicular to the noise source (the loop receives signals strongest
traveling in the plane of the loop)

The two main advantages of a Wellbrook over a tuned loop is if you are working low frequencies as well as high and not having to tune the loop remotely ....

Other than that *in it's tuning range* a tuned loop will outperform an untuned amplified loop every time as IP2 and IP3 problems are virtually non-existant unless you add an amplifier and even with an amplifier it's usually better because of the inherent filtering of the tuned loop

I'm shooting off the hip here but about 12 ft of copper tubing, a 365pf tuning cap and a remote drive for the cap and you should be in business for 4-21 Mhz ... If you need a little boost then get a Kiwa preamp w/BCB filter built-in and you'll have a system better than the Wellbrook (For your application) and still be able to pocket a couple of hundred bucks ...

If you were DXing NDB's or other low frequency signals or DXing everything from 100Khz to 30Mhz then the Wellbrook starts looking better than a tuned loop but the range you are after is perfect for a

tuned loop, the biggest problem will be rigging up a remote tuning mechanism but there are a few examples on the internet to help you out

Hello again, Metro Base!

Here are two addresses:
sales@...

www.oatleyelectronics.com

OATLEY ELECTRONICS PTY LTD,
PO BOX 89 OATLEY NSW 2233 AUSTRALIA
PHONE: 02 9584 3563
FAX: 02 9584 3561

I am still testing the 1st one of the two kits, that I received.
I will try to find a little thicker plastic box to be able to fit the
9 V battery into it with the breadboard, variable resistor and
a switch to open and close the connection to the battery.
I want to use a rechargeable battery, so perhaps I will try to
recharge it without taking it out from the box every time.
That might be best, to spare extra work every now and then,
I think. Though I can see on the schematic, that a +11 to 30
VDC current may be introduced...
In that case I probably should just add a key for an outboard
DC? Perhaps avoid totally connection to main (house) power
source and use a car-battery or even a motorcycle-battery?
At least thouse might be more durable, than small batteries,
and give less noise, than AC/DC adapters.

From the addresses in the beginning you will find pictures of
these kits also, but I will try to send photos later into the
Photos-mail-box of the Loopantennas Group and perhaps into
the Shortwave-Antenna-Yahoo-Group, too?

As for the listening: Last night I heard very clearly both 5025
R.Rebelde, Cuba and Nouakchott, R.Mauritania. 5030 Radio
Ouagadougou had finished about 30 minutes before 0000 at
UT for some reason, so I'll try to listen in to it tonight a little
earlier... 60 meter band is an obsession to me!

Thanks for interest this time.

5015. KC8AON x2 Twin Lead Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-03-06 21:35:32 UTC
From: MASH
Topic: 5015 Message: 5015

Hi Everyone:
De Cliff WW6CC. This is my first posting. I have been reading
the mail for a few months.
I made a KC8AON x2 Loop. Its a 300 ohm twin lead double loop.
It is about 78 ft., both loops total. I made a 4:1 balun for it.
Whether I have the balun in or out of line, wether I use a tuner
or not, its is infinity SWR on all bands from 80M to 10M. Any
ideas on how to solve the infinity SWR problem?
Thanks in advance,
73s,
Cliff, WW6CC

Hi Cliff,

Not sure what the KC8AON x 2 loop configuration is but I assume ... x2 refers to 2 turns in the loop, 78 ft refers to total wire length, and 300 ohm twin lead is the feed line used to feed the 2 turn loop. I assume infinity SWR indicates a high SWR ??

I am sure you will need a balanced antenna tuner to couple this antenna to your transceiver. The impedance the tuner will have to deal with depend on the frequency you set your transceiver to and the length of the 300 ohm feed line. The SWR is basically a function of the amount of mismatch between the antenna impedance and the feed line impedance. If the antenna has a 300 ohm impedance and it is fed with 300 ohm feed line there will be no mismatch, the antenna will absorb all the energy, and there will be no energy reflected back and thus no standing waves .... an SWR of 1:1.

As the antenna feed point varies from 300 ohms (up or down) there will be power reflected back thus creating SWR. Typically balanced feed line like 300 twin lead, 450 ohm ladder line, and 600 ohm open wire line are lines that loose the least amount of power due to SWR. However, no matter what the feed line, the higher the SWR the greater the loss. In order to actually predict the SWR the feed line/tuner will have to deal with you need to know the impedance of the antenna at any particular frequency and the impedance of the feed line. There are antenna analyzers that can be used to measure this. However the majority of hams simply experiment with different configurations to see what works and what doesn't.

The SWR remains pretty much constant along the feed line ... but the impedance at any particular point along the feedline will be a function of the antenna voltage/current ratios .... some of which a tuner can deal with and others that simply refuse to be matched with the tuner. So you need to compromise ... if your antenna is 50 feet away from your operating position

your feed line has to be at least 50 ft long ... can't be less hi hi ... however if you can't tune it to a frequency you really want then you might add some line to get a 'sweet spot' that will tune with your tuner.

Coincidentally, the SGC antenna tuner company uses 80 ft in what they call their 'Stealth Antenna' . They advertise that you can use the 80 ft wire in either a 1, 2, 3, and even a 4 turn loop from 80-10m. They don't use a feed line to the loop but tune it directly with an automatic antenna tuner. The tuner has to be located at the antenna feed point. A coax feed connects the output of the tuner to the operating location.

Nothing is simple hi hi.

Jim, VE3CI

5017. 20m delta beam

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-03-07 23:03:33 UTC
From: John
Topic: 5017 Message: 5017

I am in the process of designing a 2 element delta loop beam for 20m. I am wondering if anybody here has taken the approach that I am using. I going to have it in the L configuration and I plan to feed it with a gamma match (basically like the old CB V-quad design). I settled on the L configuration because what I came up with using EZNEC showed me that it would be the best for my particular installation -- I am only going to have it up at 30ft.

By doing it in the L configuration it has a good horizontal lobe from about 45 degrees to about 15 degrees and then from 15-5 degrees the vertical and horizontal lobes meet and are almost equal in strength. My thinking is that this will be a good antenna for short haul skip, as well as being good for long haul DX since the horizontal and vertical energy are close to being equal -- my thinking is this would reduce fading due to polarization shifts that are common on long haul and trans-polar paths. I could be wrong, but I believe that it is a sound idea in theory. I used a delta loop beam like this for a while on 10m and on long haul it would outperform my 6 element yagi that was about 20ft higher about 50% of the time.

Any help with this before I put the money into the antenna would be greatly appreciated.

John, KC8NTP, east central Nevada

P.S. I have also thought about insulating the elements and using a 1/4 wave section of 75 ohm coax to feed the antenna, since this a very close impendence match.

Topic: 5018 Message: 5018

I built one of these long ago and sold it in a move, sad I hadn't kept it since then.

Just found one in a used computer store yesterday! Everything there, even the book. Barely looks used. Of course the foam in the case and around the battery has turned into that tar-like goo but that's easily replaced.

It only goes down to 1.6MHz, but easy enough to make coils for it, uses RCA photo plugs for the coils.

And it only cost me $22.95! Less than I could have bought the parts to build one.

Remove all that you can mechanically. IE, scoop and scrape it off.
Careful not to rub it in.

Then use paper towels and isopropyl (rubbing) alcohol. You want as
little as possible left when you do this, as what is there turns
gooey.

Careful of the lettering, some of these things were made with
something that dissolves in alcohol. Found that out the hard way
this morning, some of the lettering on this Heathkit is smudged
now.

It has something else wrong with it, too. Hard to get an indication
on the meter with a new battery (checked, 9.6V) and drops off to
zero at the ends of the scale. It may be bad connections after
sitting so long.

Mine does this also with the 20 meter coil; it's the connection
between the coil and the meter is a little tricky. MFJ sells a dip
meter which has a similar appearance to the Heathkit, but with
different coil connectors.

The RCA female does look a bit grey.

Strangely, I cannot pick anything up on my brand new frequency
counter. I'll have to check it out on my 'scope. It was built from a
kit, after all, and it may look unused because it was built incorrectly.

When was that Heathkit Dipmeter sold?
I am always interested in how long it took for the foam
padding to turn to greasey tarry petroleum cheesecake.
I scraped some of this off a printer at work the other day,
and was amazed that that the printer dated to something
like 1990. This phenomenon has something to do with
the 'plasticizer' which makes the plastics material flexible.
Maybe some other reader can comment on the mechanism
of this working.
I have used test equipment which had a plastic carry handle,
and the handle was beginning to have that "sticky" feel which
is a sign of trouble coming. I have a large plastics equipment
transit case which would be an expensive item to buy, except
that it has acres of yukky black cushioning inside and i haven't
had the fortitude to get in there and try to clean it out. Paint
thinner removes the traces but it is a lot of work and you get
a lungfull of toxic fumes. Maybe i will default and just drag it
to the trash dumpster. -Hue Miller

5025. Pickup Loop.

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-03-10 00:58:08 UTC
From: John MacKay
Topic: 5025 Message: 5025

A few weeks ago I reported that the 8" pickup loop to my 30" receiving loop "had a life of its own". When the receiver was tuned to 17000-20000 khz the pickup loop directed local noise to the receiver even when the antenna loop was tuned as far off freq as 3500 khz.

I have since reduced the size of the pickup loop to 5", and am pleased to report that Australia on 17795 khz can now be heard without the neighbourhood bedlam. Either the noise source has disappeared or I have raised the resonsnt freq of the pickup loop + coax to a noise-free portion of the spectrum.

It was suggested at the time that I resort to tuning the main loop with ladder line and a tuner, thus eliminating the necessity for a pickup loop. I may try it for comparison later this year but my varactor tuner suits my purpose at this time. 73 de VE7AFN..

Be a better friend, newshound, and know-it-all with Yahoo! Mobile. Try it now.

Transistor and dual channel MOSFET.

Interestingly, somewhere here I still have some 40673 dual gate
MOSFETs in antistatic foam from -long- ago.

Hi,
How do I know how many turns of wire do I need for my loop antenna? In case you need the dimensions it is going to be 11 11/16 inches wide and 13 3/4 Long. I am just trying to make a basic antenna for AM Radio, but I have no idea how many turns I need to make it work right. Thank you for your time.

Don't know when this one was sold, but the one I had originally I
bought and built around 1981.

Use isopropyl to clean it out after scooping out as much as you can.
You still don't want to breath a lot of it, but it isn't as bad as
thinner.

The following is mostly unrelated to the discussion about Heathkit foam, and entirely unrelated to loop antennas ...

I just wanted to add a note, that Deet, the active ingredient in many insect repellants, also dissolves plastics.

So this could be another contributor to the handle stickiness.

My son found this out the hard way, when his camera case started to dissolve onto his hands while we were walking around taking pictures. It was a cheap camera so no big loss there, but his hands became black.

That, plus Deet's toxicity, are good reasons to use the newer insect repellants that use Picaridin instead.

Hi John,

I assume you are going to tune the loop with a single or double section capacitor ... eg about 365 pfd per section. It is an easy matter to experiment ... however for a loop of that dimension I would estimate (based on my experience with loops the same approx. size) that 16 turns will be close. I don't know if you want the lower half, the upper half, or the whole band ... eg. 540 - 1700 khz. In any event try 16 turns and see how low it will resonate with one section. If you want the whole band then prune the turns down to resonate at the low end with 2 capacitors and switch one of the capacitors out to cover right to the top of the band.

For me it is no problem since I am really interested in about 540 to 1000 khz. For me, that dimension will resonate down to 540 khz with a single 365 pfd capacitor and 16 turns.

John,
According to http://www.am-dx.com/loop_calc.htm, using your
dimensions, .25 winding spacing, with variable capacitor tuning from
14 pF to 390 pF calculates 24 turns will give 33 kHz to 1778 kHz.
You'll cover LW and MW with the loop.
Or, visit the site to test other sizes, numbers, etc.
73,
Kraig, KG4LAC

John, I have a tuned loop, 24" diagonal, 17" on each side, with 15 turns of 22 ga magnet wire, 1/8" spacing, and it tunes the entire AM Broadcast Band (MW) with a 9.6-365 pf tuning capacitor.

Here is an online Loop Calculator by group member Bruce Carter.

http://www.mindspring.com/~loop_antenna/umr_emc_calc.htm

Entering 11.69" for width, and 13.75" for height, and 16 turns, as suggested before, it shows that it should cover the entire AM band.

Entering my dimensions above, the calculator shows coverage from 430 khz to 2.65 mhz.

Entering your dimensions, with 1/8" wire spacing, and 18 turns gives a result of 427 khz to 2.65 mhz coverage, very similar to mine.

I can just get 540 khz on the bottom end of the tuning capacitor range with a little bit to spare, so you might want to begin with 18 turns. You can always take off a turn or two to go higher, but that does not seem to be a problem with my antenna. I can get stations on the top end of the band, again, with some tuning cap rotation to spare.

I also have an untuned loop, 17" diagonal, 12" on each side, which is close enough to your dimensions, that uses 4 turns of closely spaced (touching) 22 ga insulated stranded hookup wire. And while not as strong as the tuned loop, it requires no tuning for each station, and picks up quite well.

From: John
Topic: 5033 Message: 5037

I should have elaborated on that a little more clearer. I plan to have 1/3 of the antenna going vertical, 1/3 going horizontal ☐ both these parts are going to be aluminum tubing ☐ I am then going to complete the triangle with 14 gauge wire. I am then going to make another delta loop that is 5% bigger and mount it on a boom with 12ft spacing so that I can have a beam that I can turn with a rotor. Like I said in my last post, I used one of these on 10m for quite some time and have always had great luck with them. I also used one on the CB for years as well -- the one thing that I found was that I could talk to mobiles at extreme range using this antenna.

It is going to kind of be like the period example that I did below, but it going to have a different angle; I am going to bend the ends of the tubing at a 45 degree angle towards each other so there isn't as much stress at the ends of the vertical and horizontal portions of the antenna ☐ since the wire portion is going to naturally try to pull the elements to a 45 degree angle and cause undue stress at the center of the element. I also found that by bending the elements like this that I can make them slightly shorter, which changes the geometry slightly. I thought that by doing this that it would be detrimental to the performance. However, I found that it actually got about 1Db better, not much, but I will take every little bit I can get. I also found that the impendence went from about 250 ohms to 140 ohms, so now I can match it with a ¼ wave section of 75 ohm coax.

The antenna has great gain ☐ about 10Dbi @ 16 degrees take off. The best thing is that once it gets down to a take off of 5 degrees it still has better than 5Dbi and the radiation is equal in vertical and horizontal polarization. I also like that it is very usable down to about a 2 degree take off where it has -1.5Dbi gain, which is much but better than a lot of verticals have at that take off.

I hope that I was able to clarify everything for you. I thought about doing a Moxon antenna for 20m, but I have always been a loop man. I like my yagis but I always seem to gravitate back to loops at some point.

John, KC8NTP, east central Nevada

If you have EZNEC, I can send you the file for this antenna.
Just contact me at kc8ntp at yahoo

Not a good example, but I think you will get the point.

I have for sale an MFJ 1786 Loop Antenna for sale. Asking $100 plus actual shipping charges. It was on a vacation house for several months and worked fine. When I returned I could no longer get the SWR to dip. Upon internal inspection of the loop, I noticed the case on the motor had cracked. I tried to epoxy the case, but it did not cure the problem. A new motor through MFJ is $26.00. I have another MFJ loop on my main QTH and have tested the control unit. It works fine. Both the loop and the control unit are in very good physical condition other than the above problem. I really don't have time to mess with it further, and am willing to part with it for the above price.

I've been researching some ways to join my copper cap together and come across silver brazing.

From what I've read so far it seems that 56% Silver, Cd free solder should be pretty appropriate with MAPP gas and silver flux.

Has anyone had any experience with this?

tnx

I was a weldor for 30 years and did my share of brazing.
MAPP [And the last letter does not stand for Petroleum
as one idiot stated on This Old House, or other DIY TV
show] that comes in a standard Benz-O-Matic cylinder
will work for silver brazing, and if you are good it will
also work for brazing with brass filler rod.

The alloys vary as do the melting points, but most welding
supply houses will have more than one alloy to choose
from. _http://www.harrisproductsgroup.com/_
(http://www.harrisproductsgroup.com/) has a nice
list of alloys, fluxes, and FAQ's.

Do not be afraid to use what looks to be too much flux.
I have never seen too much used, but if you use too little
you will have problems. Another trick is to heat the flux
very slowly so that all the water boils out. Once the water
has all evaporated [the bubbling and spitting will stop]
you can be more aggressive with the heat. The flux
will turn water clear and start flowing nicely when up to
heat. Do not heat directly on the joint, but heat where
you want the silver to flow too. Capillary action will
draw the silver braze into the joint and produce a very
strong joint.

Cleaning the area to be brazed with a Scotch-Brite
pad is not a bad idea either but due to the higher
than soldering temperature and aggressiveness
of the flux is not necessary. If the parts brazed are
small enough, toss them in a bucket while still warm.
this will aid in flux removal. If too large for that, toss
a wet rag over the area.

I hope that this helps,

Eric

Jim,

If that is anything like the Eutectic [forget the #] alloy that melts at that
temperature, good stuff. The Eutectic flowed like water in a really thin layer. I do not think that it is quite as strong as the Ag/Cu alloys, but ought to work well. For joints that overlap there is enough surface area to provide a very sound joint.

Silver solder is another bird. I still use Harris Stay-Brite 8 for all the
plumbing that I do here. Overkill as it is strong enough for all refrigeration
joints as well. This could be an option for you too. All depends on joint structure.

5044. Ferrite Rod Loop for SW

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-03-14 18:58:24 UTC
From: Aimo Unto Olavi RUOHO
Topic: 5044 Message: 5044

Hello, the Wise ones!

I sent for ferrite rods from LY2KW in Lithuania and received 48 of 10mm x 200 mm (3/8" x 8") rods.

My question is: how to best construct a ferrite loop for lower SW, the so-called Tropical bands between 60 m to 120 m.b.?

I imagine, that it would look like a "T" to be able to rotate it on my MFJ-959C Receiver Antenna Tuner/Amplifier, on which I have made a corresponding connection for a 6 mm male jack. This works very well with my homebrew 6 mm (1/4") copper-tube-ring-loop with 30 cm (12") diameter.

I would like to use 1 mm (or less) diameter enamelled copper wire, because I don't have any Litz wire.

How many turns should be best? Should there be primary and secondary part as are common on MW and LW ferrite rods? Which end should be connected with which connection?

I made these questions not only to be sure myself, but also for them, who are making their "2nd" steps on this noble hobby....

I'm sure, that you as a large group have a lot more experience than my humble person does.

Are there available any links with exact drawings/photos to make this idiot-sure? If there are, what are they? ("Yes" is not the most wise answer for the beginners, and for sure not for me.)

73 from Aimo, the eager home brewer.

I was sent to the Army Welder/Blacksmith school in Aberdeen Proving Grounds almost 50 years ago where I learned to use "Silver Solder," along with other joining techniques. Brazing refers to the use of brass in the joints and works fine - silver solder is a great way
to join small pieces, especially jewelry but it can be very expensive compared to plumber's grade solder. Also, it requires a special flux which is painted on the components of the joint then heated until the flux dries into a crust and then when the crust reaches the temperature where it again melts the solder is applied, usually flowing like a magic stream throughout the joint. Great stuff, but probably not stronger than the cheaper grade.

I did use the silver solder about 15 years ago to build my son a racing bike frame and it works in that application also, much better than brass or tin solder.

As I recall, the Brazed joints are closer to actual welds than solder because the interface between the brass and steel/copper/etc. tend to form stronger bonds as the metals flow together.

Best of luck,

Grant

Thank you very much!

I searched my archives and found photocopies of your plan, 9 whole pages.

I understand, that our minds are working at two quite different levels, my dear friend.

You are the architect and I am the carpenter, barely capable of reading your plans, but invalid to put them into practice right away without further exact advice. That's why a really good architect usually has a work group to draw picture after picture after picture including all possible details needed for all idiots on the building place to do their job exactly as the architect had planned. Still all those idiots are the ones, who are needed to complete the common task for all to be satisfied. And all working there are happy, when the work is done.

In other words: I am a kit builder, who can not build about anything from schemes, only through point to point instructions. Still also I am very happy to be able to do my part and get things done as well as humanly possible to me at my own level.

I am very thankful to you, Chris, and all others on this group, to have received so much encouragement from you all. It may be totally impossible for you to understand, how big part of my present everyday life has been spent with you and your texts and drawings and photographs. After saying this I remain in the hope of more assistance in the future to people like myself from all of us on this group capable of giving it, from me to others, too, where possible...

73 (Best Wishes!)
Aimo

Hello Aimo,

This may be of interest to you (sorry, Japanese).
http://www.eonet.ne.jp/~doi/
He uses thick rods (including straight 4).
And you may need tapping to cover all the SW range (up to 30MHz).

Osamu

Subject: [loopantennas] Ferrite Rod Loop for SW

Hello, the Wise ones!

I sent for ferrite rods from LY2KW in Lithuania and received 48 of
10mm x 200 mm (3/8" x 8") rods.

My question is: how to best construct a ferrite loop for lower SW,
the so-called Tropical bands between 60 m to 120 m.b.?

I imagine, that it would look like a "T" to be able to rotate it on
my MFJ-959C Receiver Antenna Tuner/Amplifier, on which I have made a
corresponding connection for a 6 mm male jack. This works very well
with my homebrew 6 mm (1/4") copper-tube-ring-loop with 30 cm (12")
diameter.

I would like to use 1 mm (or less) diameter enamelled copper wire,
because I don't have any Litz wire.

How many turns should be best? Should there be primary and secondary
part as are common on MW and LW ferrite rods? Which end should be
connected with which connection?

I made these questions not only to be sure myself, but also for them,
who are making their "2nd" steps on this noble hobby....

I'm sure, that you as a large group have a lot more experience than
my humble person does.

Are there available any links with exact drawings/photos to make this
idiot-sure? If there are, what are they? ("Yes" is not the most wise
answer for the beginners, and for sure not for me.)

73 from Aimo, the eager home brewer.

Aimo,
I recently salvaged a ferrite rod for SW from an old Sears Wayfarer.
It had a coil wound on either end. One side had 5 turns, the other,
about 20. It was just bare copper wire, I'm thinking about the same

gage as what you have. There seemed to be just enough spacing between turns to prevent shorting. This rod sounds to be about the same size as one of the ones you obtained. (i'm out of town right now) Anyway, I made a "Tee" mount for it using a piece of slotted 1/2" pvc pipe. The vertical pipe was an even smaller diameter pvc tube into which a 6 mm male jack fit very nicely. This made it easy to test both loops in my Palomar base amp. I've only had time to reveal that, yes, it does work. The 20 turns tunes the whole tropical band and the 5 turns works the higher bands fairly well also. Using a Sat 800, I traded using the whip against the amplified loop and got equal results, even into the higher frequencies where ferrite loops are supposed to fall off. Higher meaning below 10 mhz. To make it easy to switch loops, I used two pairs of mini crimp lugs, the shovel nose male lug on the loop side and the female lug for the plug side. The wires from the plug run up the tube on the outside to maintain spacing. I will post a pic or two when I get home... tomorrow hopefully? Good luck with yours.

Regards,
John

Thanks!
This is the smart one selling only to USA&Canada!
I protested on these pages earlier about this unfortunate situation.
Any way, those ferrites are rather expencive...
So, I have to make my own experiences by glueing many thinner (10 mm x 200 mm) rods together. As I mentioned earlier, I now have 48 this size rods to begin with.
It is a lot cheaper to me to buy the rods I need from eastern Europe.

I started yesterday planning a turnable ferrite rod antenna. Today I sew some pieces of plastic tube to make a "T"-shape antenna to be sticked into my modified MFJ-959C's jack connection. I hope to be ready at midnight or next day afternoon...This will be the first one of an expected long row of this type antennas, I hope, from my "homebrewery".

"Next, when opening [the] southern window, [the] summer landscape ....". Aimo, you may or not know that Japanese [like Korean] is NOT a Sinitic language. Instead, there are good reasons to place both in the Ural-Altaic language group. And as you are almost certainly aware of, Finnish [like Estonian] is from the western branch of that same language group. It's quite likely that when picking up a distant broadcast of Japanese or Korean where the words aren't clear enough for recognition, the rhythm and "flavor" of it will sound vaguely "familiar" to your ear.

For the books:

What is the difference between brazing and soldering?
Brazing - The AWS defines brazing as a group of joining processes that
produce coalescence of materials by heating them to the brazing temperature and by
using a filler metal (solder) having a liquidus above 840°F (450°C), and
below the solidus of the base metals.
Soldering - Soldering has the same definition as brazing except for the fact
that the filler metal used has a liquidus below 840°F (450°C) and below the
solidus of the base metals.
Above from _www.Silfos.com_ (http://www.Silfos.com)
Eric

In a message dated 3/14/2008 5:15:18 P.M. Eastern Daylight Time,
tuquerencia@... writes:

As I recall, the Brazed joints are closer to actual welds than solder
because the interface
between the brass and steel/copper/etc. tend to form stronger bonds as the
metals flow
together.

Best of luck,

Grant

I had those coils with a MFJ249. Fine for dipping small LC pairs (tank), not so good with antenna elements. Much better results with a homebrew contact dipping adapter. Take a PL259,solder 2 inches of 12 Ga. solid into the center, and then add a 150 Ohm resistor across the connector. Gave the same results as the "test tanks" with the MFJ add-on coils, but much less ambiguity with antenna elements. Just touch your 12 Ga. "probe" to the radiator and adjust meter frequency until the meter "dips" to the lowest SWR.

Doug Kniffen

5058. 20M Loop progress

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-03-16 14:12:11 UTC
From: Jim Miller
Topic: 5058 Message: 5058

The brazing material I'm planning to use is 56% silver and 22% copper. That should make for a high conductivity attach between the copper vanes and spacers used in the stator elements of the all-copper capacitor. The remainder is 17% zinc and 5% tin. The melting point is over 1100F and the flow temp is around 1250F. MAPP gas with a high temp nozzle and just air for the oxidizer should be sufficient.

Other than the conductivity of the alloy, the important feature is that it has no cadmium which would give off toxic fumes during brazing. I plan to wear breathing protection anyway as well as set up some sort of exhaust fan. The work will be done in the garage with doors open.

Next step on the cap is to buy the hard copper vane and spacer materials, likely from McMaster, and work out the details of the fixturing to hold the assembly while brazing. I'll probably need to buy some firebrick somewhere. I also need to get a metal shear and tumbler, probably from Harbor Freight, to cut and polish the vanes. McMaster also has some teflon bushing/bearings which I'll probably get for the rotor bearings. The tuning motor will be a old RC servo for now.

I received the 0.020" x 2" x 20ft soft copper strap from TheWireman and the 1/4" OD copper tube from HD and I think I've figured out how fixture the tube properly centered within the hoop of strapping for solder attach.

My next step will be to form the copper strapping into a 16ft circumference loop with as little supporting structure as possible (mostly fishing line and a few dabs of glue) and with ends overlapped to form the tuning capacitor. The strap I bought is a continuous piece 20ft long to give me the additional length for this cap. (The strap ends eventually will attach directly to the stators of the copper butterfly cap.) That should allow me to create a reference loop to which I'll refer all my other measurements as I go along.

I want to get that reference measurement done before attaching the 1/4" copper tubing as a rib and I'll remeasure it after that attachment and after each piece is added to the assembly. That way I'll know immediately if anything I've added has spoiled the Q.

I hope to work the 20M QRP Foxhunts with the simple overlapped and ribbed version of the loop this summer while working on the cap assembly which I expect to take most of the construction effort. The bandwidth for this configuration computed by various loopcalc programs is 51Khz which is plenty wide enough to have some CW fun without retuning.

Once the cap is constructed I should be able to tune 20, 30 and 40M.

> I looking at.
> Thanks

Here is how to do it with a genuine dip meter. I would assume an
antenna tuner with a dipping coil would work the same.

Make a large loop, maybe 1 foot in diameter. Twist it at the bottom
into a figure 8, with a large diameter loop and a tiny loop through
which you insert the dipping coil. Suspend this figure 8 structure
with some tape inside your loop under test. The large loop of the
figure 8 will couple with your loop under test; read off the resonant
frequency with your dip meter coil inserted into the tiny loop of the
figure 8. You may then experimentally determine the frequency range
of your loop, by checking the frequencies on your dip meter with the
capacitor fully unmeshed, then fully meshed.

Having said this, I don't see any reason why you need to set the
tuning capacitor at a particular point prior to adjusting the "gamma
match", which is actually an autoformer, like a Variac. This is
because at all frequencies at which the main loop resonates its
impedance is the same. The "gamma match" simply transforms that high
impedance to 50 ohms. The measurement is frequency independent.

So just set the capacitor an any point. Attach your MFJ analyzer (no
dipping coil...use it as an antenna analyzer set to
Z) to the main loop and slowly move the shorting wire on your "gamma
match". When it is in the right ballpark you will note a sudden dip
in Z. Switch to SWR and find 1:1 or if you can measure R and X, find
R=50 ohms and X=0.

The AEA equipment was built in the US. There is a chance the
motor can be purchased from Mouser or Graingers. Does it
have any manufactures numbers on it? Even better a company
name? I expect they used an off the shelf motor and you
should be able to find one that will work. You may have to
remove it and make some measurments and visit a catalog or
two.
If you find one please post in the files section.

Sorry its still not clear,
"So just set the capacitor an any point. Attach your MFJ analyzer (no dipping coil...use it as an antenna analyzer set to
Z) to the main loop and slowly move the shorting wire on your "gamma match". When it is in the right ballpark you will note a sudden dip in Z. Switch to SWR and find 1:1 or if you can measure R and X, find R=50 ohms and X=0."

A. Attach 259 to loop as an antenna with coax/pl259, cap and gamma match untuned
B. Adjust Z to 50 ohms using the gamma match slide
C. Switch to SWR and tune cap for 1:1

Thanks
Bruce Vicknair

Unfortunately the motor was so badly corroded that I couldn't get any useful information off it so I though I'd ask here! I've measured it, searched the net and considered buying a motor for an MFJ loop which MFJ will sell separately but I thought I'd ask here...

Cheers,
Andrew EI3GSB

Hi Bruce,

A. is correct.

B. is correct. B is a "rough tune" of the gamma match. You
will note as you move the slider very close to proper tuning the Z
will take a sudden dive. At that point...

C. Switch the analyzer to SWR and very gingerly nudge the *gamma match
slider* (not the capacitor) to achieve SWR=1:1. This sweet spot may
seem to be very elusive. Patience pays.

The only function of the variable capacitor is to move the frequency
of the loop. By first doing A, B and C above you will always
achieve a perfect SWR no matter where you tune the capacitor.

Once tuned you will want to check the Q of your loop. Find Fo, where
SWR is 1:1. Then move your frequency (alter the variable capacitor)
for SWR of 2:1 and write down the frequency. Then find the other 2:1
SWR point by rotating the capacitor and calculate the difference. The
smaller the difference, the higher the loop Q and hence the greater
the loop efficiency. With small loops performance is all about
reducing resistive losses.

One final point. This reflector has members who build receive only
loops as well as receive-transmit small loops. The advice above might
be considered overkill in a receive-only system.

Excellent, Bruce,

Please let us know how his turns out.

If you are building this small loop to reduce local (near field)
electrostatic noise, then be sure to connect a balun between the loop
and the transmission line, so that the outside of the transmission
line shield does not become part of the antenna.

Hi, I see that mods.dk has the AEA Isoloop manual, which I just downloaded, and as luck would have it, the diagram is there. It doesn't say what the motor is, but AEA used the ubiquitous but now discontinued Motorola SAA1042 Step Motor Driver chip.
<http://www.mods.dk/downloadmanual.php?RefFil=AEA_Isoloop_Antenna_Manual.zip&radio=>

A little more digging with Google provides a college stepper motor primer (Lab 8) which provides almost the same diagram as the AEA! I guess the design was pretty common!
<http://hibp.ecse.rpi.edu/~connor/education/IEE/labs/Lab_8_Stepper_motor.pdf>

With these two things, it shouldn't be hard to find a 12V 500mA stepper motor which has specs which fall in the range of values that come from the SAA1042.

5071. Loop antenna tuner problem

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-03-20 04:11:26 UTC
From: w0bf55
Topic: 5071 Message: 5071

After being off the air for 10 years or so, I put up a big (about 500') loop antenna hung in the trees at our new place in the boonies of northern Minnesota. The loop feeds through the wall of a detached garage to a MFJ 929 Intellituner and choke balun then via coax (about 100') to the hamshack in the basement and an Icom IC 756PRO3. Every thing seemed to be working fine until the tuner failed. According to the tests, a relay was stuck. I had purchased the tuner in November 2007, so I returned it for repair under warranty. UPS delivered it to MFJ on March 3. I just got a letter from MFJ saying they looked at it on March 8 and it would be 4 to 6 weeks before repair and return. Without the tuner, I am off the air on 160 - 40 (I made a 20 m. ground plane). Being inexperienced in some of these companies, I am wondering if this is a typical response time. In a 53 year ham career, this is the first time I have had to return an item for repair. Maybe I have just been lucky. Bruce W0BF

5072. Question about variable capacitor

Yahoo group: loopantennas (2008 — 2012)

From: kg4lac
Topic: 5072 Message: 5072

Recently purchased a 381 pf variable capacitor to use when building a MW loop.
Looking at the variable capacitor, with the turning shaft facing me, there are 2 solder connections on the left and 2 solder connections on the right. I thought there would only be 2 connections on the variable capacitor, for the antenna. Sorry if this seems a dumb question, but which connections are usually used for a MW loop?
Thanks.
Kraig

>Kraig

Hi Kraig,

It sounds like your capacitor is a double ... eg ... there are two separate groups of vanes that rotate at the same time when you turn the shaft. The first pair of solder connections are connected to the same thing ... that is the stator vanes of the first capacitor. Likewise the second pair ... eg left and right are connected to the same place ... e.g. the stator vanes of the second capacitor. The other side of the capacitors ... eg the rotor vanes are connected together and are in turn connected to the frame.

If you want to use one of the pair ... one side will be one of the 4 connectors while the other side will be the frame.

However if your capacitor is a single capacitor then the 4 tabs must all be the same .... eg connected to the stator vanes. so simple use any one of the 4 and the frame.

Jim

5077. Another gamma match question

From: brucevicknair
Topic: 5077 Message: 5077

I tried tuning up for the first time on my Cu loop and was able to get swr to 1.0 but never at my frequency of interest. I tried changing the tuning cap range. I'm using two line choke baluns in series and the mfj259b is several feet away.

Is there a way to calculate the proper gamma match length?

Is the geometry a factor?

I'm using straight gamma bar(no capacitor) to the sliding contact.
Thanks

Bruce, Sounds like you are "there". If you achieved an SWR of 1:1 *at any frequency*, you should be able to shift the frequency by nudging the variable capacitor. If you unmesh the cap more the resonant frequency of the loop should go up and vice-versa. Let's say you unmesh the cap a tad; you will no longer have a low SWR. Now find the new resonant frequency by raising the frequency of your analyzer until you find the new SWR of 1:1 point, which is your new resonant frequency for the loop.

Once you have set up the gamma match for SWR 1:1 anywhere, don't touch it. Your small loop is good for every frequency tunable with the variable capacitor.

Hi Craig,

It's hard to tell from the photo exactly what you need to do. I suggest you take the capacitor and completely unmesh the plates (turn the thing clockwise as far as it will go. The part that rotates is called the rotor; the part that is fixed is called the stator.

You need to determine which solder tab attaches to the rotor and which tab attaches to the stator. You attach the loop across the two correct terminals and you are good to go.

If you rotate the shaft and the thing doesn't tune, you are probably hooked up to the trimmer. Look at the sides of the capacitor. If there is an adjustment screw, the capacitor has a trimmer adjusted by the screw. The terminal on that side will be hooked up to the trimmer, not the main capacitor. Using an ohmmeter or test light, probe from the capacitor stator to find out what terminal to use. You may be able to visually determine that. The rotor will be connected directly to the frame of the capacitor.

Hope this helps.

Yes, your capacitor is single gang, as the other fellow stated.
Connect to the frame and any of the four tabs. They are all the same.

To attach to the frame use a very short 6-32 screw. Make sure the
screw does not go through and touch the vanes. To make such a short
screw I used a brass round head screw, threaded a nut on all the way,
then (wear safety glasses!) while holding the nut with vise grip pliers
lightly clamped, cut off most of the threads with a Dremel cutoff wheel.

Try the screw, and use however many washers are needed to keep it from
touching the vanes.

I have the same capacitor without the gear drive.

Hi Bruce,

On the subject of variable capacitors for small loops, do you intend
to transmit on this loop?

If so I would advise using a butterfly or split stator (or 2 gang)
variable capacitor. This helps mitigate the resistive losses in the
single gang variable capacitor wiper. Also spacing between adjacent
capacitor plates becomes important, as you don't want the adjacent
plates to arc.

From: geo
Topic: 5090 Message: 5090

Edit: I couldn't edit the previous post so I deleted it and republish it.

I'm working on a project and it involves loop antennas. These are the preliminary works.

I've found these are able to receive (in a below-ground situation) radio stations from New Jersey (I'm in Grand Valley, Ontario).

I've also found that tuning the second loop to a similar frequency will help the primary loop capture more of the signal I desire.

I'm amplifying the detected audio with a small guitar amplifier that happens to be on hand but it will operate a small crystal earpiece I own as well.

The loop is rectangular, 110cm X 55cm, windings spaced 1cm apart. Coils are wound of 100 ft. #18 ga speaker wire, tuned with old salvaged radio capacitors I've kept since I was a kid. Taps switched at odd numbered windings to allow different wavelengths.

Detection is just with a 1N34 diode.

Below ground operation sounds interesting .... I can't even hazard a guess
hi hi

>I've also found that tuning the second loop to a similar frequency
>will help the primary loop capture more of the signal I desire.

Yes, this is of course the way you can 'boost' the signal input to an
ordinary AM broadcast station. the distance/orientation between loops is
important.

>I'm amplifying the detected audio with a small guitar amplifier that

I assume you are using a diode detector (crystal set) .... to the crystal
set fraternity adding the amplifier would be 'cheating' hi hi

>The loop is rectangular, 110cm X 55cm, windings spaced 1cm apart.
>Coils are wound of 100 ft. #18 ga speaker wire, tuned with old
>salvaged radio capacitors I've kept since I was a kid. Taps switched

That is a good size loop for MW reception.

>When I get my LC meter (it's in kit form and it's enroute) then I'll
>be able to tune the loop better to hit the shortwaves as well, which
>is my goal.

You certainly won't need 100 ft of wire for SW ... you can tune most of the
HF frequencies with a decent size single turn. However you will have to
use a different coupling system (eg mutual coupling) as most SW receivers
do not use internal loop antennas as do most MW receivers.

Have fun

Jim

Sorry, I need the amplifier to hear the signals, my wife is deaf and she was making quite a racket this evening vacuuming the kids bedrooms.

Iitially I wanted to pick up SW signals only. My employer makes a proprietary EAS design which I repair and prepare for orders daily and I wanted to learn more about how these things work so I started with 100 ft over 10 turns and have tapped it down. To my surprise I'm getting quite a good selection and performance out of this system!

Eventually I want to set up a transmit/receive situation and see how I can pick up a wave trap (essentially an EAS tag) with far simpler circuitry than these EAS systems contain.

I'm also secretly hoping that I'll come up with my own design for an EAS system I can patent, as well I'm hoping my step-son will develop some curiousity and interest about radio and electronics when he sees this rig in operation.

I have the TG35 from Tquchina on e-bay, $60 shipped. It does work quite
well. On SW I get a better signal with it than with the rod on my
Redsun RP2100. I use it mainly on MW on the RP2100 at night in bed
listening to talk radio. The 2100 is very sensitive, but the TG35 adds
that little extra gain without tuning. It's not going to get signals
that you can't hear without it. With the MW unit plugged in it draws
about 20ma, with the rod, 15ma. I use it about 2 or 3 hours a night and
have to remember to switch it off. It sits just inside a window so it
can charge all day from it's solar charger. The solar charger does not
have enough output to sustain itself. It also can be charged from a
computer USB port. I believe Kaito adds a wall wart charger. I intend
to modify it for external power, maybe from the radio. I've already
chchanged the internal 600ma 2/3 AA size battery pack to a 1000ma AAA
pack. It uses 3 cells.
Hope this helps.

There was a retired ham in Maryland that used to hand make an excellent tuned loop that he named the "Torus Tuner". He made 2 versions, one for MW and one for SW. I purchased the SW one and it works great.

He stopped making them a few years ago and looking at the ARRL ham call sign directory I see that he even has let his ham ticket lapse.

Does anyone remember these or perhaps even has one?

Tom

Hi,

I never owned one of these loops but I have read about them. Apparently he made 2 sizes for MW, one small and one large. The large one was a couple of feet in diameter and looked very much like a black hula hoop with the tuning capacitor mounted in the coupling piece that completed the circle. The hula hoop sat in a wood base and was inductively coupled to the MW receiver. Apparently he also mad a SW version ... but I have not seen and example or read about it.

I am curious how the SW version couples to the receiver as most SW receivers either use a whip antenna or use an external antenna via an antenna connector. You say you have a SW version ... you might let me know how it couples to a SW receiver.

I have built any number of tuned loops and I have one I use regularly for MW that is about the same size as his small loop. I must admit mine look pretty messy compared to Ed's sleek versions.

Jim

The lead coming from the SW Torus Tuner has a 1/8 in MONO plug on it. It plugs into the 1/8 in jack that appears on most SW portables. I also have made an adaptor consisting of a 1/8 in jack with two leads ending in alligator clips. This is for my portables that don't have an external antenna jack. I connect one lead to the whip and the other to the audio ground on the 1/8 in audio jack that is there for earphones.

Here's a tip concerning something I discovered by accident: The TT presents a HIGH impedance to the radio. This is because the tuned loop actually appears to the radio as a parallel tuned circuit. The TT will work just as well with ONLY ONE lead connected to the whip!! This is because a parallel tuned tank circuit has the same characteristics as a 1/2 wave end fed antenna. I know this works because I use it in this mode all the time. I tune in the station then tune the TT.

I will never part with my TT. I'm sorry to hear that Ed passed on. Years go I talked to him on the phone and he seemed to be a great guy.

Hi Tom,

Very interesting .... you believe (no doubt correctly) that the mono jack is simply connected across the tuned loop .... a high impedance. I have used tuned loops for SW reception and tuned them remotely (about 8-10 ft distance). I located the loop out on the balcony. I used a short length of either 300 ohm twin lead or 450 ohm ladder line between the loop (a single turn 3' in dia.). I coupled the end of the feed line to a link coupled antenna tuner (E-ZEE match circuit). I could use this arrangement to both tune the loop (5-15 mhz) and couple it to the input of the SW receiver.

The improvement in reception comes from the added gain and improvement in the s/n ratio due to high Q of the tuned loop and the location of the loop out on the balcony ... where there seems to be less RFI.

I used this arrangement for several years while living on a 9 flr apartment in a downtown location.

From what you have experienced it would indicate that a simple tuned loop located on the same table as the SW receiver (a park bench when i am travelling) can be tuned at the loop and coupled to the receiver via a single wire to the whip! I am raring to try that this summer.

Ok this might seem dumb but ;
Iv'e built two loops for am now ,one simple loop for a cheap radio i have in my office hard wired to radio ,another with a variable cap,mutual coupling for my kaito 2100 .
The question is? can ,or is it possible to make a loop for Fm?
I have'nt seen anything online about this but i would think in theory it would be possible ? Fm is just a different band ,
Ideas???

The loop would have to be one hundred times smaller in diameter than for AM reception, because the wavelength is that much shorter. Unless you specifically needed the selectivity of the tuned loop, there isn¹t much point to it, because an FM whip is so much more efficient than an AM whip of the same length, or the built-in AM wire-wound ferrite rod. And if you are looking for that selectivity, look at the ³Q² you need in the FM band vs. AM. In the AM band, your stations (in North America) are on 10 kHz spacing. So if you are tuning at 1 MHz with say 5 kHz bandwidth, you are looking at a ³Q² of 200. In the FM band, stations are on 200 kHz spacing, so if you have a BW of 100 kHz at 100 MHz, your ³Q² is 1000 so you need to have one tenth the resistance in the FM loop winding than in the AM loop winding. Because your loop circumference is one hundred times smaller, that shouldn¹t be a problem, but also consider the skin depth issue your resistance will go up (on a per unit length of wire basis) by a factor of one hundred. So the skin depth and circumference trends cancel, and that means you will need to use Litz wire with a usable cross-section area that is one tenth that needed in the AM band, to get the selectivity you want in the FM band.

Correction to last statement Litz wire cross-section would need to be ten times what it was in the AM band, not one tenth.

And your tuning cap will be much smaller in value than what you used in the AM band.

Hi Dean,

Loop antennas for FM broadcast reception 87-108 mhz are indeed not common. I certainly have not tried to make one. However if you follow normal loop logic a naturally resonant loop designed for the middle of the band would be approximately 3.2 ft in diameter and have a feed point impedance of 50 to 70 ohms. A bit unwieldy, relatively low Q and broadband, with maximum reception broadside to the plane of the loop. You could build and tune a second loop and put it in front or behind the first loop to get added gain and directivity ... even more unwieldy hi hi.

If you want to go to 'small' tuned loop design ... the usual practice is to reduce the loop size by a factor of 10 .... the loop would now be appox. 4 or 5 inches in diam. and would have to be tuned with a small capacitor. It should exhibit high Q characteristics with a sharp null broadside to the plane of the loop. Coupling would be a problem since FM receivers use either a whip antenna or an external antenna input connector. Coupling by mutual inductance would not be feasible. However I would think simply connecting a short wire from one side of the loop to the whip (use an alligator clip) would provide (high impedance) coupling.

It might be an interesting project.

Jim

I have seen simple loop FM antennas used for transmitting. Their advantage (over a horizontal dipole) is they are non-directional. They are not so common anymore as most FM broadcasters have gone to dual- or circularly-polarized antennas.

I really doubt anyone makes an FM antenna with tight selectivity in mind. Most are rather wide and cover the whole FM broadcast band, though transmitting FM antennas are tuned for lowest SWR at the intended frequency. So high Q is not important (indeed, not desirable) and no special wire or material is required.

Ham radio people also use loop antennas at VHF frequencies. Square loops are sometimes called "quads." A "quagi" is a yagi made out of quad loops.

So yes, loops are effective (and preferred by some) even at FM and higher frequencies.

Andy

Hi Dean,

Here is a second response .... with some construction ideas. Lets say you have a small receiver with a whip antenna for FM broadcast reception. Start with a wood base just large enough to allow the radio to sit on it. Install a vertical wood dowel about 1 ft high. Build a metal loop 6-8 inches in diameter with a small capacitor at its base ... I will just guess ... 50 pfd ??? This would allow tuning the loop within the range 87 to 108 mhz.

Place the small receiver on the base so that its extended whip comes up in the parallel to the loop .... at the center. You have a small loop 1 ft high on the base ... in front you have the tuning knob and behind the loop you have the vertical whip antenna from your receiver. The loop will couple to the whip by capacitive interaction. You can adjust this by raising and lowering the whip and bringing it closer or farther.

You rotate the whole arrangement base, loop, and radio to take advantage of the directional properties. If the capacitive coupling is insufficient you could solder a short insulated wire to one side of the tuning capacitor and wrap the other end around the whip. In fact the capacitive wire coupling might be better since you could put the whip all the way down which would then accentuate the performance of the loop

It would be interesting to hear how this would perform !!

Jim

In the 2-meter amateur band a frequently used type of antenna is a "quad"or a "cubical quad". It is a square loop with sides of about 20" long. It could be made circular as well. It has a single radiating element or a reflector and/or a director can be added.
The problem is that the FM band is a bit wide for a resonant antenna, but so are all Yagi's that are used very often in the FM band.

That loop is for uhf reception. If it is eight inches in diam., that is about 20 cm, so about 62.8 cm in circumference. Using lambda/10 as the criteria for max loop wiring length for an electrically small loop at 100 MHz (mid-FM band) you get 30 cm circumference for a single turn. The loop would have to be much smaller than the uhf set-top loop.

Subject: [loopantennas] Re: FM Loop.

Small tv sets often come with a separate small loop for the high bands. I have one here which measures about 8 inches in diameter. I believe that FM broadcasting is on lower frequencies so a tuning capacitor or a larger loop would be in order. VE7AFN.

Topic: 5113 Message: 5113

I recall reading somewhere that Litz wire is only worthwhile up
to something like 1200 kHz; if i don't have that figure quite right,
i recall that the frequency definitely was in the MW BC band.
That information was in a text of some sort, not a club or list
posting. I have seen an experimental FM-band loop or two
published in Wireless World magazine. The only advantage
i can recall is that it eliminated need for an external whip antenna.
In the FM band you don't have the problem of stations hundreds
of miles away coming in on the same channel, so you wouldn't
think a directional loop for this band would be so worthwhile.
Occasionally, maybe; as when you're trying to separate some
low power station on the low end, the low power station end, from
some more nearby station on a near frequency. I would think that
in the urban environment, an FM loop might not differentiate so
well as you have reflections of the signal at all kinds of random
polarization. As far as being practically do-able however, maybe so:
the US Army had a loop antenna adaptor for its PRC-6 hand-held
walkie talkie from the 1950s. This operated up to 54 MHz or so.

Well some great ideas !
Thanks Paul for the links i'm going to make that simple loop for sure!
I knew i saved that piece of coax for some thing ?
For Jim's idea i'll have to find a cap but i would like to try that one
too !
I really like the strange and wierd stuff ,now i wonder if i could make
a hot antenna out of a piece of 6'' aluminum water pipe? Let's say
about 20 feet ? long... he heh ,,can you say J pole ???

WELL!

I saw many different Small Active Loops in a near-by Carrefour Store the other day. They were for FM/VHF/UHF/TV. So you can very well use one such Antenna inside your home for FM! Their sizes were about 9 to 10" diameter. Some of them claimed 40 to 45 dB maximum amplification!

I think, after my tests, that these more modern models, many different type small VHF LOOPS, will be O.K. on lower frequences also.

I have 2 older models in my listening room, and they work very well on Medium waves giving even 9+20 dB on 855 kHz Murcia (ab.60 km) and Deutsche Welle 6075kHz 9+5 dB. Even Algiers on 252 kHz is heard well enough (S7+) from the Southern coast of the Mediterranian Sea.

I was using my YAESU FRT-7700 Antenna Tuning Unit in front of my receiver TEN-TEC RX340, not the best ever made, but in my economical situation as a retired pensioneer, good enough.

Of course these may not be good enough antennas on the lower channels, but at least according to my tests good enough for listening to LW, MW and SW stations of the world other than the most weak and rare ones!

To you Jim I would add, that just go ahead and test yourself. Don't be afraid of possible negative utterings of the "experts"! You surely will be able to build one passive Loop of 9" diameter yourself!? Thick copper wire or soft copper tube will be sufficiently good materials. Your 1st product need not be perfect for you to understand the principal idea!

Best Regards and open minds + hearts and attitudes to all folks!

Hi Dean,

Loop antennas for FM broadcast reception 87-108 mhz are indeed not common. I certainly have not tried to make one. However if you follow normal loop logic a naturally resonant loop designed for the middle of the

band would be approximately 3.2 ft in diameter and have a feed point impedance of 50 to 70 ohms. A bit unwieldy, relatively low Q and broadband, with maximum reception broadside to the plane of the loop. You could build and tune a second loop and put it in front or behind the first loop to get added gain and directivity ... even more unwieldy hi hi.

If you want to go to 'small' tuned loop design ... the usual practice is to reduce the loop size by a factor of 10 .... the loop would now be appox. 4 or 5 inches in diam. and would have to be tuned with a small capacitor. It should exhibit high Q characteristics with a sharp null broadside to the plane of the loop. Coupling would be a problem since FM receivers use either a whip antenna or an external antenna input connector. Coupling by mutual inductance would not be feasible. However I would think simply connecting a short wire from one side of the loop to the whip (use an alligator clip) would provide (high impedance) coupling.

It might be an interesting project.

So yes, loops are effective (and preferred by some) even at FM and higher
frequencies.

Andy

Some years back I build a UHF TV loop [TV signals both AM and FM
components] using a piece of 12 gage aluminum. The OD was cut
using the lowest frequency of interest and the ID was cut for the highest
frequency of interest. The centers of the circles were offset to give a
wider section at the top with the bottom around ½" which I removed a ½"
section making a gap and drilled two holes in these ends to mount the
antenna wire.

Not only did this antenna work well for UHF TV but I later hooked it to
a 440 MHz ham transceiver and it gave excellent results end fire with
a great gain increase over the stock rubber duckie antenna.

In the 2-meter amateur band a frequently used type of antenna is a "quad"or
a "cubical quad". It is a square loop with sides of about 20" long. It could
be made circular as well. It has a single radiating element or a reflector
and/or a director can be added.
The problem is that the FM band is a bit wide for a resonant antenna, but so
are all Yagi's that are used very often in the FM band.

Cor Beijersbergen van Henegouwen

For designing an antenna of this nature find the geometric frequency center.
To do that take the square root of [lowest frequency² x highest frequency²].
This will give the best results.

A 'quagi' is a yagi with a quad reflector to give it a higher front to back ratio.
An antenna made from quad loops is just referred to as a quad of X number of elements.

5125. Re: Fm question

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-03-31 15:19:36 UTC
From: patfrompagosa
Topic: 5103 Message: 5125

Receiver antenna designs for the 87-108 MHz commercial FM band are available on the web. These include loop designs. FM tuner hobbyists are always slightly tweaking them. I've collected a bunch of URLs, but am providing only a couple below.

Building these antennas is a fairly harmless addiction. Dimensions are typically multiples of, or the same as the folded dipoles made from 300 ohm twinlead that are provided with FM tuners on purchase. Most common are single loop 30" or 60" (approx) squares with either 300-75 ohm twinlead or coax leadins. Connections are variously made at the middle of one edge, or at a corner.

Less common variants add a 1/4 square reflector loop. A popular version can be found at http://www.wryr.org/Antenna_instructions.pdf. Still less common are arrays of more than one square, typically to form a cube.

I'd suggest you consider joining the Yahoo FM Tuner group. Members vary from very experienced engineers to amateur listeners like myself. At any time, you will get helpful advice on any part of FM broadcast receiving. Many members will help you with your antenna questions.

I have never seen any flaming on that group. Two members in particular have extensive antenna experience. Bruce carter AND Brian Beezley.

Bruce has a web page at http://www.mindspring.com/~brucec/bg.htm He discusses antennas extensively there. BTW, His AM loop calculator is at http://www.mindspring.com/~loop_antenna/amloop_calc4.htm

Brian Beezley's page is http://ham-radio.com/k6sti/index.html There, he has provided calculations for a variety of antennas. He also has a simple leadin balun he recommends - at http://ham-radio.com/k6sti/balun.htm

Brian last year published an "accidental design", with superior performance, BUT I lost that exact URL. You can get to the string from http://tech.groups.yahoo.com/group/FMtuners/message/44646 once you join the FM Tuners group.

Hope this helps

Pat

5126. A loop for longwave and mediumwave

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-03-31 17:01:14 UTC
From: heinzd777
Topic: 5126 Message: 5126

Dear Gentlemen,

I'd like to build a simple loop antenna for listening to longwave and mediumwave radio stations. I have not much space, so I think of using the same loop for 150 to about 1700 kHz. Is this possible?

What I have is 100 m of antenna wire, 0.7 mm diameter, a variable capacitor from 20 to 1360 pF and two Sony receivers, the ICF-SW77 and the ICF-2001D. On the online-auction monopolist with the four letters I bought a second variable capacitor, 2x350 pF today.

I thought of a wooden square frame of 80x80 cm with inductive coupling of the radio, for this is the most simple, and I don't want to spend too many Euros.

Can you help me?

Thank you!

Heinz from Germany

This note corrects a term I usedincorrectly jn my earlier post, and also directs you to the Brian Beezley optimized cubical quad design I referred to.

Correction:
For the antenna design at http://www.wryr.org/Antenna_instructions.pdf I mistakenly called the inner square a reflector. Sorry for my amateurish misuse of terms.

Additional information:
I located the URL for Brian Beezley's optimized 88 MHz FM Cubical Quad. It is at http://www.wryr.org/Antenna_instructions.pdf

This antenna consists of a square reflector loop, a slightly larger active loop, and a 1/2 length smaller square in the corner of the active loop. This small loop is critically spaced. The leadin is attached at a critical point between the active large and small loops. The two big loops are also critically spaced from each other. It should not be too hard to build using a PVC pipe or wood frame, But I have never built it. There are probably people on the FM Tuner web that have built one.

Hi,

Well yes, that is possible. However, you will almost certainly not get that tuning range with one configuration. You will have to build in some kind of switching. You have plenty of capacitance to play with and certainly plenty of wire. A loop 80 cm square is a good size which should provide reasonable performance. Inductive coupling works vy well and will allow excellent coupling adjustment .... which does effect performance.

As far as switching is concerned there are basically 2 strategies .... start with a fixed capacitance ... eg your 20 to 1360 pf and work it with sufficient inductance to cover the lower portion of the range ... then with the switch ... short out turns to reduce the inductance is one or two steps to cover the higher portion of the range. Conversely, You can start with a smaller capacitance and inductance to cover the high end of the range and then switch in additional capacitance in one or two steps to cover the lower portion of the range.

The easiest way to accomplish the switching is with 'electrical clips' to either short out inductance or add in capacitance. Certainly that is the way to go while you experiment. That capacitor you have 20 to 1360 has a pretty large range. You might try it first ... eg ... use only enough inductance to resonate at the top of the range (1700 khz) with near minimum

capacitance. Then see how low it will go with the maximum 1360 pf. I have heard some loops will cover almost the whole mw band with a single 365 pf capacitor. It should go down below 540 khz ... experiment to see how far.

beaulieupat@... writes:

This antenna consists of a square reflector loop, a slightly larger
active loop, and a 1/2 length smaller square in the corner of the
active loop. This small loop is critically spaced. The leadin is
attached at a critical point between the active large and small
loops. The two big loops are also critically spaced from each other.
It should not be too hard to build using a PVC pipe or wood frame,
But I have never built it. There are probably people on the FM Tuner
web that have built one.

Hi Eric,

I built a cubical quad for 20/15 back in the late 50's or early 60's using bamboo ... which was used in shipping carpets. It sat on a guyed 30' TV mast which i rotated with a pipe wrench. It worked DX like you wouldn't believe .... but then that was at the peak of the all time best sunspot cycle hi hi However conditions aside ... the quad was one of the nicest HF antenna I ever used (but then I have had the privilege of using a large rhombic) .... it was quiet, broad band (xmitter liked it) and signals just jumped right out. The problem was it was rather high maintenance.

Nice Jim,

Size wise the quads are hard to beat. I love the pipe wrench rotator! After my heart there. I am awaiting some nice weather to see what I can come up with for antennas. I have lots of TV mast and 1000' of polyester rope to hold things steady. Never built an HF quad to date, but plan on that too. I have toyed with them on VHF though. Nice.

By high maintenance was that due to the bamboo or wire breakage? Was not too much of an issue with VHF, but a lot less flexure there.

I have seen some designs where they preload the spreaders with the wire to bow them which eliminates some of the problems. That would add more stress to the wire tough. Having been there let me know what you think.

Last good cycle I was building a Ten-Tec six meter FM transceiver and the instructions for pre-aligning the receiver section called for you to tune into the strongest station that you could find. Found one that sounded to be a local. Shoot, He was in Florida and I am in Ohio. Picture me with this radio with no complete transmit section yet! Glad that is not on film.

Thanks for the post,

Eric --KB8TJR

Hi,

As with most things when you go big everything is magnified .... a quad for 20m is approx. 17' per side. I arranged the spreaders so they would be on a 45 deg angle to either the vertical or horizontal plane. The distance from the center to each corner is exactly 12'. I tied on small metal fittings to the ends and spread thin flexible braided type copper wire around the 4 corners (approx. 68' total) ... I fed the center of the bottom horizontal portion with 72 ohm balanced line. The 72 ohm balanced line (they don't make it any more as far as I know) came down to the shack and a 1:1 voltage balun (made by Heathkit from air-dux coils).

It was a perfect match ... and the antenna will take any legal level of power you would wish to put to it.

I used approx 6' to 8' for an aluminium boom. I used a second loop as a reflector ... and tuned it with a piece of open wire line for maximum front to back ratio. I later mounted a second set of loops within the first loop for 15 m and fed it from the same feed point with the same feed line. I never noted any deterioration in performance.

The only maintenance problem was ICE .... the antenna was very gud in the wind, but if there should be freezing rain with a build up of ice load the whole thing will droop like a wilted flower. The other problem was general weathering of the bamboo ... eg getting dry and brittle over time. The whole thing is quite light.

The spreaders in this arrangement are not under much tension. I used home brew flanges at each end of the boom to clamp the 4 bamboo poles for each loop. The tricky part is building this thing and then getting it up there. My 30' tv mast was made of 3 pieces that would nest together. I could build and adjust the antenna on the top of the 10' piece then push it up by hand. the bottom of the mast sat in a smooth cup on the base ... and

the guys were attached to rings that allowed the mast to turn. so the only thing holding the antenna from turning was the friction in the cup at the base. The 2' pipe wrench was more than enough to rotate the whole mast/antenna assembly.

The quad worked very well on 20m at 30' height. A friend of mine had a quad on a 60 ft tower (a commercial quad ... GEM quad) and it was exceptional.

Jim, VE3CI

Jim,

More good stuff, thanks,

One thing that I have thought about for deicing loops is to run a low voltage, low current through them. Would work with the driven element but wiring up the reflector to do so would be a trick. Not too much can be done with the spreaders either.

The fiberglass might be an improvement over the bamboo. I am sure that is debatable too. Bamboo is hard to beat other than the weathering issue that you mentioned.

I am also thinking about a modified loop in the shape of a diamond rather than a square too. That would allow a bit more distance from the ground. Doing so might make the longer spreaders rather unwieldy though ... more thought needed.

Thanks for the construction details too.

Eric -- KB8TJR

5135. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-04-02 00:30:21 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 5135

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

Date: 2008-04-02 22:13:32 UTC
From: Bob Warren
Topic: 5133 Message: 5139

Hi Eric
Don't forget polarization. A cubical quad fed at the bottom is 'horizontal' and fed at the side is 'vertical'. Noise tends to be 'vertical' so you are better to keep the conventional feed point at the bottom.

5140. Narrowband FM reception

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-04-02 23:06:38 UTC
From: Ken Javor
Topic: 5111 Message: 5140

Not directly a loop-antenna related question, but I just lost a portable AM/FM radio that while not particularly sensitive, had high enough FM channel selectivity that it could receive a weak station in the presence of nearby stronger stations. I have been unable to find a replacement with the same selectivity, and now it is difficult or impossible to get the weak channel because the stronger ones are bleeding over. Any suggestions out there? I used to have a Yamaha receiver with adjustable FM bandwidth, but it was hardly portable.

Thank you,

Ken Javor

5141. Pipe Wrench Rotator

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-04-02 22:37:15 UTC
From: palindrome3993
Topic: 5141 Message: 5141

The pipe wrench rotator described by Jim, VE3CI, is an upscale variation of the "armstrong" rotator. Years ago in ham radio circles, turning a mast using only your hands was referred to as an armstrong rotator because it required strong arms, especially when the antenna on top of the mast was large and/or heavy.

I'm not sure if the term still exists today, but my first rotator as a newly-licensed novice in about 1968 was an armstrong. Upon hearing a DX station, I could run from the basement shack to the mast next to the garage and back again in record time.

A lot of us use GE Superadio 3's for long distance AM and FM reception. It has a tuned RF stage on FM, which gives it better than usual sensitivity. It also has a ceramic filter in the the FM IF - which can be changed out for a narrower version. I have done so in mine, and can easily separate out adjacent frequencies.

The same type of filter mod can be done on any portable that uses a ceramic filter in the IF, but the performance may not be as good as the GE.

I have a number of crystals - all new - that I can make available for anyone who needs some.

The crystals are 3.9, 4.3 and 4.4 MHz.

Alternately if you have any old (1920s, 1930s) QST magazines or other electronic parts for barter (variometers, coils, FETs, older tubes, varactors, PLLs - I run my own small home electronics lab as well so I'll be keeping a number of Xtals), I'd be willing to hear offers.

I like barter over cash, it's just easier I think.

Thanks.

Hi Ron,

Doesn't your beam rotate ?

Jim - VE3CI

5148. Twin Coil antenna in the "Patents" section and combining transformer

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-04-07 00:28:35 UTC
From: mal1958au
Topic: 5148 Message: 5148

Hi,
I have spent some time reading the different files and a large number of posts within this group.

I would like to build an antenna similar in concept to the Twin Coil antenna in the patents section. I just want it to cover the Broadcast band.

I have read and understood the posts about copyright etc about the patent, so understand the implications.

I do not intend to build the pre-amplifier or the varicap (varactor) section of the design. I just want to wind the coils and use a conventional variable capacitor etc.

However, I am stuck with the combining transformer. The text in the patent is quite obtuse at this point and as I am not "skilled in the art", don't know where to start on how to design the combining transformer.

Has anybody built one of these antenna's and if so, how do you work out what to use for the "combining" transformer ?

Cheers,
Mal (from Oz)

PS : I would appreciate the design principle and the maths etc, as locally (to the US) recommended ferrite cores etc may not be available in Australia where I live.

Hello Jim,

If you are looking for an antenna only for rx, you can use a loop with armoured amplifier, it is excellent for rx, it operates in the range of 1800 to 30,000 mhz mhz.
Hugging, ha .... See the picture, is the yelow.

I'm confused here. When you say 15 element beam, i'm assuming that
you're referring to a VHF beam? You're trying to receive stations on
14.300 Mhz on the backside of a VHF beam? Or maybe it was a typo and
you meant to say 5 element beam instead of 15 element?

If i misinterpreted your post, i apologize. But, it sounds a little
confusing the way it was worded.

HI!
Have you seen the new photos of the Twin Coil Ferrite AM Antenna sold by C.Crane?
I just added them to the photos of Shortwave-SWL-Antenna@yahoogroups.com, so if you are a member there...
I would have purchased the same ferrite rod from Amidon, but as it costs $US 10 + mailing! I'd bought 4 of more of them, but it would have made my square-formed directive antenna too expencive! So I sent for 8 rods from Lithuania, found them good enough, then purchased 40 more, The eBay man Gintaras Sakenas, LY2KW, claimed, that some body had told him to be useing such rods up to 28 MegaHerz (Mc/s)!
So I've since homebrewed 5 different antennas from them and having plans to test many more... I even used SuperGlue to join two ferrites from their ends! A better signal on LW and MW and directive on lower SW. Two of such parallel - even stronger signals!

Best Regards from Ami

Hi, all!

The Ferrite Rod seller is found by name: kwtubes in eBay. http://stores.ebay.com/KW-TUBES

I purchased 40 ferrite rods of type 10/200 mm for a total of $US 100.60 post paid to Spain. Item: 380001268208 Large balun ferrite rods 10x200mm. Lot of 40 Quantity 1 Prise $84,60 USD My first "test" purchase was a Lot of 8 rods (Item 190107598527) I also purchased 1 Lot of Hermetic Rotary Switches, 1 lot of Ferrite Magnetic Loops (2 rods), 2 Lots of 2-gang Air Variable Capacitors and 1 Lot of DPDT Power Switches 220VAC/3A//127VAC/5A, Box of 35 (200207029487) for only $US 18,95 with postage and handling. Good enough stuff at least for me!
I paid through PayPal, but the seller will accept other types of payments also.
Very quick and friendly, polite and trustworthy seller.

Best regards from ami

Hi Ami,
Do you have the eBay item number or other information, for the Lithuania
ferrite rods you purchased? I'd like to try to buy some.
Thanks,
Steve

I purchased from kwtubes several years ago. At the time PayPal would not accept non-US merchants so I had to use Western Union or something like that. All told, though, it went far smoother than I expected it to go. Just as you said -- fast, friendly, quality merchandise at a very good price. I would buy from him again without hesitation.

I just wish I had actually gotten around to using the ferrite rods the way I intended.

From: dean_0_way
Topic: 5156 Message: 5156

Well i finally got around to making my first styro loop ,been saving a Omaha Steak box for a while .It's about 14'by 16' started with 28 turns of 20 awg wire,spaced at 1/8 inch, added a 365 air cap , then trimmed to 21 turns to get it tuned ,tunes from 520 up to about 1560 and does help a tiny bit up to 1620 , this cap is a dual one , now im wondering if i should use both sides ? or would i have to add more turns of wire ? to use both .
And would doing that give me more signal capture.
Only reason i ask is there seems to be conflicting info around ,i remember reading that spacing is not that important ? and some are using different resistance caps ,
I'm not so concerned with 1560 and above just wanted to see if i can make it better?

tell me you thoughts on spacing, and other .

Using both would reduce your high end slightly as the minimum capacitance would now be double (assuming both are the same size). However having double the maximum capacitance the tuning range would then fall below your present minimum of 520 khz (leaving the inductance of the loop as it is). The specific answer to your question is that you would have to remove some inductance not add to it.

>And would doing that give me more signal capture.
>Only reason i ask is there seems to be conflicting info around ,i

>tell me you thoughts on spacing, and other .

The capture area of your loop is defined by its physical size for the most part, and not its electrical characteristics. After you have decided on the physical dimensions of your loop, "14x16" in your case, you will have closed the issue of capture area. Further design concerns relate to tuning range, circuit Q, and coupling to the radio. Circuit Q seems to be the prime design criteria. You can find lots of reading on the internet dealing with circuit Q. In most general terms high Q is related to characteristics such as 'sharp null', high gain (i use the term loosely), maximum noise reduction (narrow band pass). Design features that contribute to high Q are minimum resistance in the coil and highest quality in the tuning capacitor.

The circuit Q is then compromised when you couple the signal in the loop to your radio .... it becomes a balancing act .... on the one hand keeping your loop signal at its maximum while at the same time draining signal through coupling to your receiver. Some of the experts in this area are crystal radio hobbyists .... although they may not use loops as their primary antenna ... the tuning inductors are quite large and they strive for the same kind of performance. There are some vy interesting crystal radio sites as well that display construction practices directly related to

loop design.

Yes!
I wanted to show those bad photos here also, so you don't need to go to the Shortwave-SWL-etc. at all!
Just find the photos down here at the corresponding cathegory, if you are interested.
73,
ami

aimo ruoho <aimounto@...> wrote:
HI!
Have you seen the new photos of the Twin Coil Ferrite AM Antenna sold by C.Crane?
I just added them to the photos of Shortwave-SWL-Antenna@yahoogroups.com, so if you are a member there...
I would have purchased the same ferrite rod from Amidon, but as it costs $US 10 + mailing! I'd bought 4 of more of them, but it would have made my square-formed directive antenna too expencive! So I sent for 8 rods from Lithuania, found them good enough, then purchased 40 more, The eBay man Gintaras Sakenas, LY2KW, claimed, that some body had told him to be useing such rods up to 28 MegaHerz (Mc/s)!
So I've since homebrewed 5 different antennas from them and having plans to test many more... I even used SuperGlue to join two ferrites from their ends! A better signal on LW and MW and directive on lower SW. Two of such parallel - even stronger signals!

Best Regards from Ami

mal1958au <lewis.family5@...> wrote:
Hi,
I have spent some time reading the different files and a large number of posts within this group.

I would like to build an antenna similar in concept to the Twin Coil antenna in the patents section. I just want it to cover the Broadcast band.

I have read and understood the posts about copyright etc about the patent, so understand the implications.

I do not intend to build the pre-amplifier or the varicap (varactor) section of the design. I just want to wind the coils and use a conventional variable capacitor etc.

However, I am stuck with the combining transformer. The text in the patent is quite obtuse at this point and as I am not "skilled in the art", don't know where to start on how to design the combining transformer.

Has anybody built one of these antenna's and if so, how do you work
out what to use for the "combining" transformer ?

Cheers,
Mal (from Oz)

PS : I would appreciate the design principle and the maths etc, as
locally (to the US) recommended ferrite cores etc may not be available
in Australia where I live.

You rock. That's why Blockbuster's offering you one month of Blockbuster Total Access, No Cost.

Thanks Aimo (and the group),
As it happens I am also a member of the Shortwave-SWL group, so I was bale to see the pictures.

After doing a bit more reading, I think, I am going to have to learn about coil Q's and bandwidth etc based on ferrite core properties for the combining transformer.

Cheers,
Mal (from Oz)

Thanks for the pictures Ami.
How does your home brew ferrites work compared to the CCrane Twin-Ferrite?
How does your BCL loop work compared to other antennas (I have one too - want to know if I can build a better active loop).

Mark

Thanks for interest, Mark!
At present I only can give you rather good (?) results of the CCrane antenna: 567kHz /kc/s (Murcia): S9 + 50 dB; 855kHz (Murcia): S9 + 55 dB; 1053 kHz (Arabic): S9 + 35 dB; 1539kHz(Elche/Elx): S9 +35 dB.
My Copper tube Loop gives (without any amplification) 567 kHz: S9 + 2dB; 855 kHz: S9 + 5 dB
Ferrite rods give without amplification about S6+AM/MW, but better signals on SW than MW/AM. Signal is usually quite acceptable of quality...

If you mean with the BCL antenna the one, that I built of the Kit from Australia, I will tell some results here: Tipaza, Algeria on 252 kHz, Murcia 855kHz (the battery exhausted, I guess?)
I have to make a decent rod for MW, which really is not of my main interest.
((It may be possible, that I used a wrong type of PVC tube in my prototypes? This grey type possibly includes metal of some kind?I have to buy the suggested red tube instead or use the ferrite rods just covered with paper and tape?))
The Ferrite Magnetic Loop Antennas from Lithuania give a lot better signals on MW. I have to put one of the two, that i received, into a decent box to easier use it as a directive antenna. These rods are covered by coils made of Litz, which I don't have here.
The received results obviously depend on the ATU or Preselector used with? I have to make a lot of further tests, I guess... That will take more time.
Sorry for not found any real DX this time!
Thanks for interest and Best Regards from Ami

During the process of making some loops for different radio's i keep coming up with variable caps that aren't labeled so i began to wonder if there is a way to find value of these.
I did some looking ,on e.bay etc. for a tester that reads capacitance ,and don't see anything that says for air capacitor .
I know there are many types of caps ,can , coil etc. so i need to know if a digital tester is the way to go or is there some special testor for air caps ?
Seems rather dumb to you experts , but i like to know how things work

Thanks in advance

Hi,

The best way to test the value of variable capacitors or any pfd value capacitors used in RF circuits is to use standard values of capacitance and inductance. Then you need some kind of device such as a noise bridge and receiver or something like the MFJ antenna analyzer. The objective would be to combine the unknown capacitance with a known value inductance or vis-a-versa. Your noise bridge or antenna analyzer would be used detect resonance at particular frequencies. Then calculations from formulae would be used to determine L or C as the case may be.

However with experience you can eye ball variable capacitors and estimate capacitance, range, voltage capability etc.

Jim

Hi, Dean_o!
I have the same problem. I have been looking for a multimeter or -tester for both inductance and capacitance, but until now I haven't found a cheap enough unit. They are usually about $US 100, more or less, new.
If someone knows a cheaper one to be sold, I'd be glad to know about it.
Preferably from continent Europe or Asia, because usually mailing costs + customs fee raise the price too high, when purchased from USA...
I saw one or two sold by RadioShack, but for 50 - 70 $US. For over double price mailed to me in Spain, so out of the question!

Good hunting!
Ami

Capacitor is a capacitor, so why not? Only those +/- capacitors make an exeption.
I may be wrong, though...
By the way, from which address can I find those cheap Capacitance Meters?
I tried to google, but did not find.
Thanks and Best Regards,
Ami

I've seen photos on E-Bay with a digital capacitance meter displaying
a value when connected to an air variable so I think they would work.

I still would like to hear from someone that has actually done this.

Please & Thanks,

Jeff

Thanks, Paul!
Looks very good to me, but too expencive even as a Kit for me!
I purchased one cheapo from Hongkong via eBay a few minutes ago in the hope, that it will fill my humble needs. It is a LCR bridge meter, so it will show the inductances, capacitances and resistances.
I have to print out your email, thanks!
Best regards again from:
Ami

Subject: [loopantennas] variable caps

During the process of making some loops for different radio's i keep
coming up with variable caps that aren't labeled so i began to wonder
if there is a way to find value of these.
I did some looking ,on e.bay etc. for a tester that reads
capacitance ,and don't see anything that says for air capacitor .
I know there are many types of caps ,can , coil etc. so i need to know
if a digital tester is the way to go or is there some special testor
for air caps ?
Seems rather dumb to you experts , but i like to know how things work

Thanks in advance
Dean_0

Dean-0

to a capacitance tester a capacitor is a capacitor and so you can test air caps with the same effectiveness as other kinds. Likewise vacuum caps.

Depending on design, electrolytic caps may pose a problem to certain testers but air caps are definitely NOT electro's - go for it!!

Here's a design idea for your own tester for capacitors in the low range 10 - 600 pf.

Wind a loop that will work roughly in the MW range. Tune it with a fixed capacitor of known value - say 100 pf. Use a low tolerance capacitor.

Using your AM/SW radio, find the resonant frequency of the coil/capacitor combination. (Tune the radio until you get a peak in the noise). This is your reference resonant frequency. From here you can calculate the inductance value of the coil from the formula F(resonance) = 1 / 2 pi sqrt(LC).

Now substitue your known capacitor with the unknown capacitor and find the resonant frequency again. By subsituting the known inductance of the coil into the resonance formula you can derive the unknown capacitance.

For air-variable capacitors, find the resonance when the capacitor plates are fully meshed and then fully unmeshed; this will allow you to calculate the range of the capacitor.

Any guys new to electronics please heed the words of a guy who has been in the business for over 50 years. Electronics is maths!! Learn how to transpose formulas, how to calculate small and large numbers using indeces and the basics of trigonometry (sine, cosine, tangent). You can look the individual formulas up on the 'net but you need to understand how to manipulate them. Your success rate will be far higher if you can do the math before putting the work to the forge.

Ray

Thanks for also my question being answered by you, Ray!
It helps a lot to be sure to know, that probably also those cheapo LCR Meters made in China will be able to show the start-, in-between- and end-capacitances of variable capacitors. I am also glad about the fact, that from now on I'll be able to build more exact coils, because I can measure their inductances with the cheapo, too.
Less than $US 20.00 post paid to Spain really won't be too much money at this time of cheap Dollars in Euros...(1 Euro=1.57$$)
Best Regards,
Ami

Ray Phillips <ray@...> wrote:

to a capacitance tester a capacitor is a capacitor and so you can test air caps with the same effectiveness as other kinds. Likewise vacuum caps.

Depending on design, electrolytic caps may pose a problem to certain testers but air caps are definitely NOT electro's - go for it!!

Here's a design idea for your own tester for capacitors in the low range 10 - 600 pf.

Wind a loop that will work roughly in the MW range. Tune it with a fixed capacitor of known value - say 100 pf. Use a low tolerance capacitor.

Using your AM/SW radio, find the resonant frequency of the coil/capacitor combination. (Tune the radio until you get a peak in the noise). This is your reference resonant frequency. From here you can calculate the inductance value of the coil from the formula F(resonance) = 1 / 2 pi sqrt(LC).

Now substitue your known capacitor with the unknown capacitor and find the resonant frequency again. By subsituting the known inductance of the coil into the resonance formula you can derive the unknown capacitance.

For air-variable capacitors, find the resonance when the capacitor plates are fully meshed and then fully unmeshed; this will allow you to calculate the range of the capacitor.

Any guys new to electronics please heed the words of a guy who has been in the business for over 50 years. Electronics is maths!! Learn how to transpose formulas, how to calculate small and large numbers using indeces and the basics of trigonometry (sine, cosine, tangent). You can look the individual formulas up on the 'net but you need to understand how to manipulate them. Your success rate will be far higher if you can do the math before putting the work to the forge.

I couldn't agree more. Any capacity tester worth its weight in salt uses a simply resonance check against know value inductors. The calibrated dial or readout simply does the calculation for you. Unless you are in a situation where you need to do hundreds of calculations I would (and have) spent my money on devices like the antenna analyzer. I also have switch boxes with know values of capacitance and inductance. All you need to do is hook the unkown capacitance in series with known inductors and check the frequency of resonance. Then punch the values into your calculator and voila! you have the answer.

But the analyzer can be used in many other useful ways other than simply checking capacitors.

I looked at that inexpensive LCR meter from Hong Kong, on eBay (item 160226853854). It will work great for measuring large and small values of capacitance, and will do the job for something like an air variable capacitor, however it won't work at all for measuring small values of inductance, like loop antennas. Note that the smallest scale is 2 millihenry (full scale reading). Small values of microhenry inductance, such as loop antennas have, won't accurately be measured. Notice the picture shows the meter measuring a 12 Henry old iron core choke. This meter will work well when measuring such large values of inductance; anything over about 500 millihenries will read fairly accurately. I have a similar B&K LCR digital meter--it won't accurately read anything under about 500 millihenries. To accurately read small values of inductance you need a meter like the aade.com LC meter, which has already been mentioned as being very suitable both for small inductors and capacitors.

I am not sure, if the following story is true:
"There was an electronics engineer, who was very bright to design complicated electronics scemes, but was totally unable to put together a simple crystal receiver."
And, when a professional electrician died, there was written the following text on his gravestone: "Paljon tinasit - paljon pilasit!" ("You tinned (soldered) a lot and ruined a lot!")

Mathematics is a very useful scientific field, but often theory and practice are too far from each other... What is beneficial and practical for one individual, is far away from another person's interests and abilities. Still the latter may invent new things, even in electronics, by just experimenting the "hard" way, if he has a burning zeal, but not much education or understanding of theory.
But, ofcource, mathematic ingenuity coupled with superb skills of making things with own hands is something to admire, even if a rather rare quality.
Just my thoughts...

This too is much ye load of old bollocks, and much beloved by the uneducated.

These hypotheses, calling them theories would be giving them too much
credence, would suggest that the zealous, but ignorant, experimenter will succeed
despite his ignorance.
Unfortunately, if he doesn't know what he's looking for to start with, he
sure as fuck won't know when he's found it!!

Sorry Ami, I'm a great believer in experimentation but get really pissed off
when it's suggested that theory and practice are quite so far apart.
The best, and the luckiest, experimenters, often know an awful lot before
they start.
For some reason this group seems to attract as many burks and also rans as
the gotta have a gold mains lead audio gits but please don't make a virtue out

of ignorance.

Edison was essentially self-taught, with his two passions being reading and experimenting. That's a FAR cry from being "uneducated"! And his Menlo Park Lab, where most of the inventions attributed to Edison were developed, was LOADED with 'braniacs'. Math? He made up for his lack of math by hiring a mathematician.

"Because of all his new inventions, people started calling Edison the "Wizard of Menlo Park." He said that "if [he] was a wizard at anything, it was surrounding [himself] with the best." Edison chose assistants he thought knew more about a subject than he did. For example, he hired a mathematician because he had never learned math.": http://www.gelighting.com/na/home_lighting/gela/students/history_bio_edison.htm

I'm not sure what "evolution", "global warming", and other such far-right bugaboos are doing in this discussion, but I seriously doubt that those whackos would have felt fully at ease with Edison. He is quoted with: "Religion is all bunk!"

You misunderstood my point, and may be confusing "education" with the
attending of school or college.
Knowledge should be an outcome of education, and I include self education
and experience in that, whether it be from study or from learning as one goes
along.
If you know nothing about a subject to start with, and lack the tools that
will help you understand it, that doesn't stop you learning but it can make it
much more of a struggle, depending on how far you want to go with it.

Generally though, the assumption that "experience" alone is automatically
enough to achieve anything is still a load of old bullshit.
Experience still needs to be paired with having the ability and brains to
learn from that experience.
If you need to build 100 square wheels to convince yourself that square
wheels aren't very efficient that might suggest you're not learning very much
from your experiences with square wheels..

The old idea that the man who invented the light bulb was really
"uneducated" is again a load of old whatsits.

If my lack of knowledge offends you ? Tuff! joining this group is
my window to knowledge about radio's and loop antennas , if we seem
to talk about things that you already understand , Good for you ! I
never claimed to know it all ? but i'm trying to learn as i go .

Of course it doesn't offend me, and "learning as we go" is all any of us do,
but having the right tools makes it easier, and knowing at least some of the
maths is a very useful tool, as is having the intelligence to understand it.

There's plenty of radio enthusiasts who enjoy the hobby without having a
maths or electronics background, do you think I'm suggesting they shouldn't?

You shouldn't be quite so sensitive and ready to take things personally, my
reply wasn't to you and didn't even mention you.

I would hope I didn't offend Ami either but I do get a bit wound up, not that you would have noticed:-), with comments such as--
"
Still the latter may invent new things, even in electronics, by just experimenting the "hard" way, if he has a burning zeal, but not much education or understanding of theory" --

No doubt it's true up to a point, but if this zealot is to invent anything worthwhile he needs the brains to learn from his experiments, which means by the time he does invent something worthwhile he can no longer be said to lack education or an understanding of the theory, at least in the sense of its practical consequences, hence the argument fails:-)

BTW Ami, many thanks for the tip re the Lithuanian ferrite rods, mine are on their way:-)

5198. Big Wheel Antenna for VHF 6 meters

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-04-14 13:14:07 UTC
From: mantermeadows
Topic: 5198 Message: 5198

I'm searching for plans to build a 6 meter Big Wheel. These are sometimes called cloverleafs. I don't find that the big wheel has been discussed on this forum. It consists of three full wave loops fed in phase from one central point in the center and the three loops are fanned out at 120 degrees from each other. It is an omni-directional horizontaly polorized antenna and typicaly has about 2 or 3 dB gain over a dipole. It's great for SSB work where you don't want to keep swinging a beam around to hear everyone in the roundtable. Does anyone have some contruction plans or know of a link to this project?

I am sorry!
I have a very peculiar way to make myself so badly misunderstood!
I never even emagined, that ignorance is better than knowledge.
Did someone read my emails too hastily again?
It might be so, that some people want to see something, that doesn't exist, because what they read or hear in a hurry doesn't please them?
That's the main problem, when we have different backgrounds. (I only have 14 years of official general education, so obviously that is not enough?)
Finland is internationally admired of having a very high standard of schooling system. Schooling experts from many European countries as well as from the whole world want to know, how we do it, and make excursions to Finland to learn and study our system... I understand, if this knowlwedge is not a possession of all people?
I admit, that many times I have managed to write down something, that is not too pleasant to people, who are proud of their understanding, but have very low self control?
So I have to apologise again?
No bad feelings after reading these lines, I hope?

interests and abilities. Still the latter may invent new things, even
in electronics, by just experimenting the "hard" way, if he has a
burning zeal, but not much education or understanding of theory.
But, ofcource, mathematic ingenuity coupled with superb skills of

making things with own hands is something to admire, even if a rather
rare quality.
Just my thoughts...
Best Regards from:
Ami

This too is much ye load of old bollocks, and much beloved by the uneducated.

These hypotheses, calling them theories would be giving them too much
credence, would suggest that the zealous, but ignorant, experimenter will succeed
despite his ignorance.
Unfortunately, if he doesn't know what he's looking for to start with, he
sure as fuck won't know when he's found it!!

Sorry Ami, I'm a great believer in experimentation but get really pissed off
when it's suggested that theory and practice are quite so far apart.
The best, and the luckiest, experimenters, often know an awful lot before
they start.
For some reason this group seems to attract as many burks and also rans as
the gotta have a gold mains lead audio gits but please don't make a virtue out
of ignorance.

regards

Nigel

Hi group,

Eduardo unintentionally CC'ed the portuguese message bellow to this group.

Just to inform you, the message mentions the most important brazilian
ham and SWL fair. It will take place in Indaiatuba, near Sao Paulo
between July 25 to 27 2008. We invite you to visit us at the fair if
you, by chance, will be visiting Brazil these days.

More is available (sorry, only in portuguese) at:
http://www.fenarcom.com.br/

I received this yesterday.
L.B.Cebik contributed to the SWL a lot of work on the subject of the design of antennas.
You can find it on www.cebik.com

Cor Beijersbergen van Henegouwen

To the Announcement List:

==========
Folks:

This is the saddest announcement we have had to make:

It was discovered this morning that LB Cebik, W4RNL
had passed away.

He was a friend to us all and will leave behind
a great void. His beloved wife, Jean passed several
years before and he missed her greatly.

He was my friend and associate for 10+ years and I
shall always remember him for his warmth and kindness.

A tribute to this "kind and gentle giant" shall
appear in my column in the next issue of antenneX.

Thank you for your so kind and gentle email(s), Richards!
By the way, I haven't heard anything from you for a looong time!

I hope, that you are in good health?

Yes, I finally gave up, sort of "gave my little-finger to the devil", because I am a very anxious-to-know-person.
Yesterday my mailman brought to me - finally - the "WOLDS-BEST-WELLBROOK-ANTENNA, WELLBROOK ALA 100M!
I think, that it is very expencive!!!!!!!!!!!!!!!!!!!!
But it is a really good antenna amplifier. If I only were living in a better place...
I just wonder, what could be heard on a lonly island without electricity, using as power source a car-battery? Or on top of those Spanish mountins?
What I did as a preliminary test, was connecting the amplifier with my 2.5 m x 2.5 m coaxial loop on my northern wall in my listening room. I'm going to test it with my 1.5 m x 1.5 m loop on my western window-wall this evening, if time (wife) will allow...

All, that is written in the Passport to World Band Radio-book, was true! Except, that I really had no difficulties else than using a led-torch and kneeling to find and reach the coaxial-ends of the loops on my walls behind/under my radio- and computer-tables. So many wires and cables and connections in my room! (Keeps the 70-year-old limber!)

The ALA 100M Amplifier is probably a stronger version of the plain 100 1st version, because it amplifies the radio signals in an unexpected way?
Also it gives a wonderfully good S/NR. The signal is not only strong and clear, but also pure.
This toy will probably give me many ours of interesting listening
Last night I heard 4905 kHz Radio Chad in French language so nice with S9 - S9+20dB, that I'd like to turn to it more often to learn more French.
There was also on 5995 kHz a transmission from Moldavia, which I happened to hear for the 1st time in my life.
The Arab world opened itself wide open on Medium wave channel in their own language, which is one of my new hobbies... They are going to conquer the radio world with the Chinese and others little by little, as the western world is diminishing and terminating their foreign services! Stupidly enough!

Thanks for setting the mark for me with your bold example, Richards, by telling about your ALA 100M. (I still have no contact with the original producer, because I used the sales@... only, which is another person, if I understood it right.)

Best Regards from Ami,
Aimo Ruoho.
Richards <jruing@...> wrote:
Good Day Aimo -- I am sorry you have had poor luck
communicating with the man at Wellbrook. He was very
helpful to me and answered my several e-mail messages -

both before and after I purchased the product. It was a
very good experience for me.

The reason he wants your credit card number spread out
over multiple messages is to give better security and
to help protect your privacy. That is a nice thing, and
not an inconvenience, to me.

I agree PayPal is very convenient, but it costs the seller
money to use it - it is free to buyers. Also, PayPal is
not without problems for sellers and buyers, and some sellers
have decided its problems are not worth the price and that
cancels out the convenience to them. It is much better for
buyers than for sellers.

I recommend a glass of good red wine, a hunk of good
bread, and some sunshine. Maybe some lamb stew...
That should help you feel better.

Happy trails my friend. /// Richards ///

Just found my copy of a handy little book that i put someplace to
remember where i put it?
After my capacitance tester came i had to figure out what all those
symbols meant .
Anyway it's called a (pocket Ref) by Thomas J.Glover ,you should find
it at a hardware store ,mostly for builders , but has an electronics
section with math formula's and even capacitor-resistor color codes !~
I suppose there is better more detailed reference out there but for
now this is all i need .

Dean_0

post your fav,s i may need a more complete book later ?

I have in my PDA [Sony TH-55], several excellent programs that might be of value for such reference usage. In particular, I have a NEAT resistor color code program which works both ways. Since the display is in full color, it's particularly useful There's also the familiar Ohms Law wheel. And like so many excellent programs running on the Palm OS, it's FREE. My smartphone [Treo 700p] also uses the Palm OS, so I'll put it there too.

If you have a PDA or smartphone that's always at hand, check out the internet for such programs. Here's one of many good sites: http://www.handango.com/

From: Tom
Topic: 5212 Message: 5212

Hi loop fans,

I've replaced my loop tuner.

It was a 1500 watt MFJ-998 auto tuner with remote, 4:1 balun.

Now I'm using a 1500 watt Ameritron, ATR-30 with an internal, 1:1 balun.
The ATR-30 is a manual tuner and better at matching my loop to my amplifier
at 900 watts output.

See the revised diagram of my loop antenna with tuner at:
http://ph.groups.yahoo.com/group/loopantennas/photos/view/199f?b=2&m=f&o=0

Cheers.

5213. I'm new and I want to build an antenna for SW listening

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-04-30 03:44:43 UTC
From: snakeblackvegas
Topic: 5213 Message: 5213

I got a Panasonic RF 2200 and I want to start listening to SW broadcasts. Right now I have a hard time even hearing the atomic clock time broadcasts and I can sometimes hear a religious station or two. I want more! I need an antenna.

I used to sit up all night when I was a kid tuning though the static on an old Philco floor standing AM radio, listening for far away broadcasts and watching the green eye. I was in Michigan and would listen to Larry Glic on WBZ Boston. I want to search for some goodness again in short wave listening.

I live in a ground floor apartment so no outside antennas. I live in the South Western US now and the external wall and windows, including a large sliding glass door all face South West.

I looked through the files here and on the SWL group group and saw, well, lots of stuff. I admit I am confused.

I can build anything you kind folks could describe to me, but I can't fill my apartment with strange constructions either.

I saw the gamey leg loop using the existing aluminum window frame and it seems interesting, and pretty easy too but will I be able to pick up all the 3.9 to 28MHz range? I saw a lot of other stuff too though and I don't know what to do.

I'll build or buy (shudder) whatever will do the job as long as you kind and knowledgeable folks can agree on what I need. So help a brotha, and spoon feed this noob a good antenna design so I can search through the static all night long again like I did when I was a little kid.

Maybe look into something like these kits. Lots of fun to build, and will help you in your specific situation.

http://www.elexp.com/kit_aca1.htm
http://www.uoguelph.ca/~antoon/circ/AA7/activant2.html
http://www.northcountryradio.com/Kitpages/actant.htm

I built one of the north country kits and it works pretty good! It works so good that my nephew "appropriated" it for his use :)

Hi,

I am not familiar with the Panasonic RF 2200 other than seeing pictures. I assume it is possible to connect an external antenna for SW (other than the built-in whip). I assume the problem is that the RFI (noise) overwhelms the desired signals. You can confirm this by taking your receiver to a quiet location (like a park table) and check out reception with your built-in whip. If reception is adequate then you can be assured the receiver is capable .... and the problem is the receiving environment in your apartment.

The solution to a noisy receiving environment is to either put your antenna outside where it is quieter and carefully couple the antenna to the receiver via a shielded cable or to use an antenna that is selective so that the signal to noise ratio is improved. A tuned loop antenna is selective (e.g. has a narrow bandwidth which increases the desired signal while reducing the broadband RFI). Such antennas have sharp nulls ... which allow it to be oriented so that the most offending direction for RFI can be nulled.

First determine your receiver is capable of reasonable SW reception ... eg take it to a quiet place for evaluation. It is possible to provide an external RF amplifier to perk up your receiver performance. However everything I mentioned above still holds ... Providing an external broadband RF amplifier will amplify both the desired signals and the undesired RFI (noise) by the same amount. In fact the increased RF input due to the external amplifier may add to the problem by introducing front end overload leading to distortion.

Steve Greenfield has a web site that discusses building simple coax tuned loops for SW reception.

Jim

P.S. http://www.kr1st.com/swlloop.htm shows a simple receiving loop. I
have used a similar arrangement while living in a large apartment
block. It is a great improvement over the built in whip. It increases
signal strength and reduces off frequency noise with a substantial
improvement in S/N ratio.

Date: 2008-05-01 20:58:46 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 5217

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.
http://members.cts.com/king/j/jlkolb/site/dif_fet.pdf

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

* Select-A-Tenna Model #541M (Passive)
- - - http://www.selectatenna.com/

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.
http://ecforster.netfirms.com/LpAnt/Doc1.html

Very Low Frequency (VLF) Up-Converter
STORMWISE: Palomar VLF Converter allows you to use your ordinary ShortWave Radio to listen below the AM Broadcast Band. Directly Tune VLF Stations of 10 KHz to 500 KHz using your existing ShortWave Radio. The VLF Converter easily connects between the Antenna and the Radio.

5219. Connecting My Selec-A-Tenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-05-01 16:08:32 UTC
From: logically_spock
Topic: 5219 Message: 5219

I want to hook up my Select-A-Tenna for MW up to my
Palstar R30. It has no ferrite rod inside so I need to use a "couple
loop" or try to pry open the antenna and hook up a direct feed to the
50-70 ohm S239 connect or the high impeadence long wire in the back of
the radio.

Thanks

5220. Re: Complementary Push-Pull Amplifiers

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-05-02 02:42:10 UTC
From: na_no_tu_be
Topic: 4914 Message: 5220

Hi

I am on may way to build the Complementary Push-PullAmplifiers and i have a few questions regarding this amplifier.

Can i use the 2N2907A and the 2N2222A ? " Those (A) version are more available here" or it is better to stay with 2n2907 and the 2n2222.

I am a little bit surprise to see those to-92 for the Push-Pull output! Is the to-18 "metal case" a better choice for his power dissipation ?
Regardless the power dissipation, there is some indication to not use metal case transistor for the Push-Pull output?

Regarding those " Ivan board ", there is a ground plane on the other side and who make these prototype boards ?

Thanks in advance for your collaboration and excuse my English.

Gillis from Montréal

The amplifier you're asking about is the one that I designed. Yes, you
can use the "A" versions. They have slightly better performance.

If you feel the need, you can use the metal ones and attach heat
radiators. I didn't noice any adverse heating in the ones I made.

You can use the metal (TO-18) ones just as well as the plastic (TO-92)
versions. The metal ones are more difficult to obtain and usually cost much
more than the plastic ones. You can also use the PN2222/A and PN2907/A,
which are the Fairchild TO-92 equivalents.

Yes, it has a solid ground plane on the reverse side. You can obtain
the Ivan board material from:

Hi Chris.

First of all, thanks to take the time to answer my questions and to make this design available.

Do you have any ideas what can be the noise figure of both version of your Push-Pull Amplifiers.

I am curious to see if the one with only one transistor connected to the input is less noisy than the one with two transistors connected to the input ?

It will be in the vicinity of 4-5dB.

```

They should both have approximately the same gain and NF. The advantage to the complementary JFET input stage is the improved distortion performance.

From: jdh1812
Topic: 5224 Message: 5224

Howdy all. My name is John and I just joined the group. Although I'm new to the group, I'm not new to loop antennas, or antennas for that matter.

I've been a licensed ham since 1986 and my current call is AB4MS. I love to experiment with loops and find the box framed, tuned loop to be a thing of beauty, both electrically and aesthetically! I know, I'm weird.

I added some photos of a MW BC loop I built a few years ago in case anyone is interested.

http://ph.groups.yahoo.com/group/loopantennas/photos/browse/ec46

My next project is to build a broad banded loop for VLF/LF with a roll off around 500 KHz. I would like to get similar results to a Wellbrook loop if I can.

Look forward to reading all the words of wisdom that I know flow across these lists! ;)

John,
Welcome to the group.

Does your homebrew loop cover 530 to 1710 kHz?

Able to post plans, construction details?

Thanks and 73,
Kraig, KG4LAC

Hi Kraig. Yes, the loop covers all of the AM band and 160 meters as well. I have an alligator clip that I use to tap different turns depending on what band I'm interested in.

If you go to the photo section, under "John's Corner", you will see a couple of pics and there is also a simple schematic with the design details. The only thing it might need to make it better would be a low noise pre-amp.

The loop uses 1/4 turn link/inductive coupling so it maintains good symmetry and has deep nulls for noise rejection.

It's nothing earth shattering, just something I threw together in an afternoon but it seems to work well so I'm happy with it.

In the planning stages right now are plans to build the "Mother of all Loops" that will cover VLF/LF. I'm looking forward to building this loop and will be pulling out all the stops! :)

Regards,
John

John, thank you!
How about a loop for SW above 1.6 MHz up to 10 MHz or so?
Would it be directive?

Hi Aimo. Once signals get sky borne then directivity goes out the window. The main advantage then becmes nulling out the noise.

5229. Loop Configuration Question

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-05-08 14:38:47 UTC
From: Jason
Topic: 5229 Message: 5229

I seem to be having a problem with a loop install at my new house. Hoping someone can help out:

Here are the details:

a) 272' of stranded 12 gauge wire in a relatively rectangular shape.

b) Van Gorden Antenna Center Insulator connects the 12 gauge wire in a tree.

c) 450 OHM 14GA Van Gorden Ladderline connects to my Insulator on one end and connects to a HI-Q 4:1 Balun on the other end.

d) From the 4:1 Balun a coax run goes into my shack on a Kenwood TS480SAT rig. (auto tuner)

I can tune just fine on 10, 15, 20, 40 meters! (even 160 and 6 meters tune at certain locations) Audio and SWR are perfect.

However, I cannot tune any higher than 3.800 on 75/80 meters. I have cut down the ladder line and no change. When I cut down the ladder line I tuned in the other bands perfectly. Ladder line sits at about 93 feet in length now. I tried cutting down further and I ended up taking out all the bands, so I reached the limit I believe. I put back the last piece I cut and now back to where I was.

I thought maybe the hardware store made a mistake and my 12 gauge wire was short. So I added 25 feet to it in the middle. It actually made 75/80 meters worse, as it didn't want to tune above 3.700. So I reverted back.

Any thoughts on what is happening? I seem to be stuck at 3.800. I don't know if this frequency, exactly, is telling me something? Any suggestions would be greatly appreciated!

That's funny you should mention such a plan. I too have been contemplating/dreaming of a similar loop project which I affectionately refer to as "The Attic Monster" loop, placed in the attic of course! I have yet to build my first pedestrian loop though, and must do this before embarking on any more amibitious loop projects. I'd really like to hear more details about your monster loop design, plans, etc. Please keep us posted, thanks.

Probably a silly question, but seeing as how 3.8 MHz is the band limit in
the UK at least this couldn't be a tuner restriction by any chance?

Jason,

How long is your coax run into the shack? Maybe you are having some nulls in the tuning?? I find it interesting that you can tune 160 but not 75/80. If your coax run into the shack is too long you are going to have some losses. It shouldn't be over 15 feet maximum, but I'm not sure if that is a contributing factor to your tuning issues.

Hi Jason and the Group,

I'm using a 250 foot loop, but with a 1:1 current balun, which is conveniently located inside my ATR-30 manual tuner. My 4:1, external balun does not work well with my tuner and loop.

The ATR-30 is a C-L-C, T-match configuration with the 1:1 current balun on the output of the tuner. See these diagrams:
http://ph.groups.yahoo.com/group/loopantennas/photos/view/199f?b=2&m=f&o=0
http://ph.groups.yahoo.com/group/loopantennas/photos/view/199f?b=3&m=f&o=0

Hi Jason,

I would shorten the loop to around 250 feet which is closer to a full wave on 3.8 MHz (468/F*2) and feed the loop directly with coax or use a 1:1 balun. Feed point Z of a full wave is somewhere around 100 ohms and you're increasing what your tuner sees by a factor of 4, that might be a tad much for your tuner to handle.

Good luck with whatever you decide. It's all about experimenting!

Wow, thats sounds like a great start! Perhaps you could add an electric motor, steering mechanism, and remote control servos to allow "custom positional tuning" from inside the house eh? That might deserve a patent of some kind...

The loop can MUST be fed in one corner for it to act as a multiband antenna.
It must be more than one wavelength on the lowest frequency.

I thought about a couple of electric servos for azimuth and elevation, I'm still debating that.

We'll see.

Wow, thats sounds like a great start! Perhaps you could add an electric motor, steering mechanism, and remote control servos to allow "custom positional tuning" from inside the house eh? That might deserve a patent of some kind...

Be a better friend, newshound, and know-it-all with Yahoo! Mobile. Try it now.

Hi Bob,

Just curious, why do you say a loop 'MUST' be fed at a corner in order to act as a multi band antenna ?

In general, a loop of any circumference is going to present the same load impedance to any particular frequency regardless where you place the feed point around the circumference.

If the loop is supported in a horizontal fashion the usual practice is to provide the feed point near the support closest to the shack, and in the case a rectangular/square configuration it would be a corner as it is much easier to support the feed line and prevent 'sagging'. Such an antenna will work well from the fundamental frequency (1 wavelength) and up. In terms of performance (load impedance or radiation pattern) there will be little difference regardless where that point might be.

However, if the loop is configured in a vertical orientation and a substantial distance above ground the load impedance again remains the same regardless where you feed the loop. However when fed in the middle of the side vs middle of the bottom the polarization tends to be vertical and horizontal respectively. If the vertically oriented loop is brought close to ground as in a Delta Loop the feed point is almost always near the bottom. The antenna will also work multiband with little noticeable difference in load ability where you feed it at its lower portion. However radiation pattern and performance improves if fed at one of the bottom corners ... experimentation shows this performance peaks when the feed point is moved up a little higher from the lower triangle corner.

Now I have never tried feeding a Delta loop at the top corner .... but I don't expect it will be much different from the point of view of loading. Performance though might be interesting.

Hi Jim
Thanks for your comments, you are correct.

I went back to my wire antenna handbook and the article states it MAY be fed in the corner not 'must' be.
In hindsight I fed mine in the corner because it was convenient but that was a long time ago.

Newby in here but know about RF; antennas etc...
Has anyone built a 6' or so loop for AM broadcast? I'm looking to
recieve 621Khz Radio National from Melbourne 350Km away. I'd like to
compare notes on what I have already done.
Hugh .. Ex VK3Z.. call long ago.

There is an interesting loop demo on Youtube. The same fellow, I
think NZ'er, demonstrates a 2' loop and a 4' loop. He says the 4'
loop was not any better performer than the 2' loop, or not as much
better as he had expected.

http://youtube.com/watch?v=QpGXECoY6zg 2' loop pt 1

http://youtube.com/watch?v=6HRZcTL15ZA 2' loop pt 2

http://youtube.com/watch?v=HXQeZxeCJ2c 4' loop

I wonder where the point of dimishing returns actually is.

Hugh; 6 foot loop for AM? Overly large and gangly, IMHO. I built a loop w/ 3.5ft effective radius and compared it to my trusty 2ft diameter loop. Yes, a little more gain. But such a monster antenna compared to the two footer. And seriously, only a few dB gain - only useful during daytime DX. At night every frequency is "too alive" to see any benefit from the larger loop. 2 ft loop uses 15 turns and a 12 to 365pf tuning cap. The large loop - 12 turns w/ similar tuning cap.

Hope that helps,

Mark

Hi,

I have inadvertently tuned a 20m quad loop (30' in the air) to the MW band and recall it was an excellent antenna even though it was not resonant. I fed the loop with a balanced feed line and experimented by adding capacitance to the end of the feed line to obtain resonance. Performance improved dramatically with resonance. However the loop was built and used for Ham radio and I only recall that one experiment.

Since then I have built a number of much smaller tuned loops for MW broadcast reception. I live in a relatively isolated community which had only one MW broadcast transmitter on 580khz (it went off the air this year) which now makes it a great location for MW dx listening hi. There are a number of MW stations about the same distance ... e.g. 250 to 450 km. Now that I have no local QRM I can also use a long wire to assist. However the long wire is not effective unless it is used in conjunction with a high Q tuned loop which acts as an efficient antenna tuner.

However if your listening environment has local MW QRM (local stations close to 621khz) the long wire is not a good idea. My most effective small tuned loop was only 2.5' square. However it was able to provide good reception of stations at 560khz and 610khz both 300km distance with my local station pounding away on 580khz. With the local station now defunct I can listen to these stations with a smaller loop that I keep on the table out on the deck. The loop is only about 15" square. I couple it to a sensitive AM receiver (with an internal ferrite loop antenna) by mutual induction.

If your environment is such that a long wire antenna out in clear is a possibility and local QRM close to 621khz is absent you can use it by connecting the end of the wire to one side of the small tuned loop. You must provide a ground connection to the other side of the tuned loop. The ground doesn't have to actually be connected to ground ... I found a short length of wire laid out on the ground to be sufficient. Couple the small loop to your sensitive receiver with mutual induction.

If your environment doesn't allow this strategy a larger tuned loop will be adequate ... however a 6' probably would be overkill. Try 3' and i am sure you will find it adequate.

Let us know how you make out.

Thanks to all of you for your previous replys on my questions regarding the big loop antenna. Things have changed and I have been blessed with opportunity to fulfill 2 of my dreams. #1 is being able to have enough land at my disposal to put up any antenna that I desire. The close 2nd is dog training. Anyway, I want to be able to have a 160 meter loop and feed it with ladder line. My thought is to support the loop on all 4 sides with 50 feet of cyclone fence posts, stuck together and guyed with dacron rope. I have plenty of room for this monster, but my questions are.....what will my supports do to the performance of the antenna (should I use the fence post approach, wood or pvc around the fence post as an insulator) and should I feed this with 450 ohm or homemade open wire line. If homemade, then what should the spaceing be? My tuner is the MFJ 974HB going to a Icom PRO 3 running 100 watts for now. As far as the feed line length goes, well, it can be as far away from the house as it needs. Thanks again for your reply

In my opinion and experience there is no detectable difference in performance between those antennas supported by metal or non metal supports. The general rule for HF antennas is "as high and as in the clear as possible". The difference between 'most' commercial balanced feed-line and home made balanced feed line is its performance during wet weather. In almost all cases an antenna fed with balanced feed line will be carrying power with some level of SWR. The result is that the antenna/feed-line system is 'tuned', and water on the feed line de-tunes the system. For amateur purposes I have not found this to be a problem ... a small 'tweek' of the antenna tuner knob and it is 're-tuned' with no detectable difference in performance.

The reason most commercial balanced line is susceptible to wet-weather de-tuning is due to the use of the molded plastic insulation used for structure/support .... which makes it much easier to use. Non-susceptible line uses a more delicate construction that represents a minimum of material between the parallel wires. If you are construction a high power remote station this is what you want ... e.g. tune it and forget it hi hi.

Scott,

I don't think you'll see a any significant impact form the metal poles; probably none at all.

The homebrew ladder line "may" provide a broader SWR than commercial 450 ohm line. But, given you're balanced tuner, I'd opt for the 450 ohm commercial window line. W7FG offers "real" open line around 600 ohms for a good price.

Put it up, and have fun.

Check out photos of my loop on page two of photos. It is 4 1/2ft. sq. I saw a photo of someones loop and modeled it from that. Using a regular tv antenna tripod it stands almost 10 ft. I added the section on the front later. I get phenomenal results. I pick up all the local medium wave signals very well and also pick up thru 12,000+ hz foregn radio signals. It wss easy to build. the hardest part was stringing the 12Ga. wire. It has withstood 65 mph winds with no problem. Good Luck with yours Ed Dawson

5249. 621Khz loop

Thanks guys, I'm fired with enthusiasm.
Mark, I said 6' 'cause it would fit thru a doorway and maybe I could make one as a peculiar kind of shadow cabinet on the wall with radio in one nook. I have an external one going that is 10' 5 sided made from fibreglass electric fence 1/2" rods and tv ribbon, but it is a bit floppy. Fed unbalanced top coupled 33pf to the AM side of a car radio. works fine,and surprise it rejects the electric fence splatter that shows up with wire antennas. Daytime 621 clear as a bell and no apparent overloading at night.
Liked the utube Paul, I'm looking for clear listening tho, low noise.
Ed, your beasty shows coax eminating from your tuner - How are you coupling into the loop?

If the radiation pattern of a loop is a bi-directional, figure-eight pattern, then i can't see how reversing the connections would have any effect on the antenna.

I could be wrong, though.

IMHO there could only be a notionable difference if this antenna were to be used together with another antenna and a phaser. Because the phase of this antenna signal would be reversed it would influence the directivity of the combination.

Topic: 5253 Message: 5253

I have a place to make a BIG loop for my HF radio.
I am looking to use for 160-10 or 6/2m even if possible.

I have aprox a 50x100x50x100 spot to place some #12 up in air.

What I am looking for in help is length and any suggestions on do's
and Don'ts for this style of loop.

they will be mounted in corners at prob. 20' to start on metal poles
and a pully system.
fed to radio tuner with 450 ladderline all the way to tuner.
from all the reading I have done figured this was best way.tuner does
have bal in it and it will handle 300 w (MFJ-269) also have plenty
more yard for length on the 100' if needed can add another 25 to 30 ft
more if needed.

is there a calculator for HF lengths and not 1 of these all tech
programs that gives me 200 things and none means a thing to a new guy
like myself.
I will be xmit max 110w for now but later on would like to boost that
up also. so I like o consider that in the initial setups so i dont
have to make a whole new setup later on.

I have read alot and laid this out on paper but still not 100% sure on
length of the total wire. I know 300 feet will work but is it a proper
length to start out with and would I need to trim it and such.

Also have not found much info on how to tune a loop or for that matter
what freq to tune it to for the most bang for my buck. it does not
have to be a 160m but be nice to have that ability.
prefer 1 wire in air so not to piss neighbors off with a crap load of
wires running around and such.

next concern is RFI to folks around me. would you suggest a filter or
anything like this to help if needed.
this is a small town and not everyone has cable and I really dont
wanna fight on my hands if I can do something 1st time over waiting.
at least the FCC and anyone else cant say I didnt do all I could do to
fix my end and to be proper setup.

ok I will start with this message see where it takes me and then ask
more as I go. I will be building this antenna middle of June 2008 in
S. TX so need a good solid antenna for hurricane season and the bad
weather they get alot of.

I do have dual band j-pole and a 6m par loop so if wire cant do those
bands its ok. just be easier on 1 antenna is all.

thanks for any and all suggestions and if anyone has a pic or 2 of
such a setup I would love to see the connections and feed side to radio.

From: John Hoopes
Topic: 5253 Message: 5255

For true multi band operation an antenna has to be non-resonant or have one heck of a good tuner. Tuning out the high reactance at even multiples of a wavelength is difficult to do.

What I have used in the past is a non-resonant loop. Basically you design the loop at the lowest frequency of operation by using the formula 1005/F and install a 600 ohm resistor in the center of the loop, opposite of the feed. Use a 600 or 450 ohm ladder line and feed with your tuner. Some power will be lost in the resistor but it will tune slick willy on any frequency up to and including two meters.

John

ke5htb <ke5htb@...> wrote: I have a place to make a BIG loop for my HF radio.
I am looking to use for 160-10 or 6/2m even if possible.

I have aprox a 50x100x50x100 spot to place some #12 up in air.

What I am looking for in help is length and any suggestions on do's
and Don'ts for this style of loop.

they will be mounted in corners at prob. 20' to start on metal poles
and a pully system.
fed to radio tuner with 450 ladderline all the way to tuner.
from all the reading I have done figured this was best way.tuner does
have bal in it and it will handle 300 w (MFJ-269) also have plenty
more yard for length on the 100' if needed can add another 25 to 30 ft
more if needed.

is there a calculator for HF lengths and not 1 of these all tech
programs that gives me 200 things and none means a thing to a new guy
like myself.
I will be xmit max 110w for now but later on would like to boost that
up also. so I like o consider that in the initial setups so i dont
have to make a whole new setup later on.

I have read alot and laid this out on paper but still not 100% sure on
length of the total wire. I know 300 feet will work but is it a proper
length to start out with and would I need to trim it and such.

Also have not found much info on how to tune a loop or for that matter
what freq to tune it to for the most bang for my buck. it does not
have to be a 160m but be nice to have that ability.
prefer 1 wire in air so not to piss neighbors off with a crap load of
wires running around and such.

next concern is RFI to folks around me. would you suggest a filter or
anything like this to help if needed.
this is a small town and not everyone has cable and I really dont

wanna fight on my hands if I can do something 1st time over waiting.
at least the FCC and anyone else cant say I didnt do all I could do to
fix my end and to be proper setup.

ok I will start with this message see where it takes me and then ask
more as I go. I will be building this antenna middle of June 2008 in
S. TX so need a good solid antenna for hurricane season and the bad
weather they get alot of.

I do have dual band j-pole and a 6m par loop so if wire cant do those
bands its ok. just be easier on 1 antenna is all.

thanks for any and all suggestions and if anyone has a pic or 2 of
such a setup I would love to see the connections and feed side to radio.

Hi Tom,

I am sure in hooking up all the different loops I have experimented with I
must have reversed the connections a couple of times hi hi. But, by virtue
of the antenna and the feed line being 'balanced' there is no significance
to reversing the connections.

Hi,

The simple formula I have used to calculate the circumference of a full size loop (full size means naturally resonant at the frequency of choice) is 1004/f (mhz). The loop is naturally resonant at one frequency ... the frequency at which the circumference equals 1 wavelength. If you want the loop to be useable on more than one band the practice is to make it naturally resonant at the lowest frequency you use and then tune it (using your antenna tuner and feed line) to the higher frequencies. You mention you have 300' available for the loop. This size will accommodate a naturally resonant frequency in the 80m band.

If you started with natural resonance at say .... 3750khz the loop diameter would be 1004/3.75 or 267'. If you want to start at 160m, say 1.9mhz then the circumference would have to be 1004/1.9 or 528'.

It doesn't mean it won't be useable at 160m but it will be tricky to load/tune ... especially with power.

Almost all horizontal (skywire) loops are a single wire. Building such a loop with 2 or more turns is technically possible but would not make it any better except perhaps easier to load at a lower frequency. As pointed out above if you have sufficient room for a loop with a fundamental or base natural resonance at 80m. You would have to feed it with a balanced line if you wish to use it on higher frequencies (multi-band 40-20-15-10m) and an antenna tuner.

If you are using a modern transceiver then there will be adequate filtering of harmonics. If you have concerns about the equipment you can purchase what is called a low pass filter LPF ... but they aren't used much these days with modern gear. However this all depends on your radio feeding the antenna tuner with a 1:1 SWR. In other words the tuner/feed line/antenna combination represents 50 ohms resistive, the load for which all modern radios are designed. After this, concerns of TVI etc will be related to how much power your run. A perfectly clean station may not cause RFI at 5 to 100w ... but cause problems when you run 300watts. No fault of the radio gear.

Hi John,

I am not sure what significance the word 'TRUE' has in differentiating one multi-band antenna system from another hi hi. There are many ways to skin a cat ... so to speak ... and designing an antenna with resistive termination is one way. Don't get me wrong ... I love terminated antennas .... and one of my all time favorite antennas was a terminated horizontal loop as you describe ... except it was quite a bit longer than 1005/3.8m. It was in fact diamond shaped ... making it a rhombic. Very directional and not very rotatable hi hi. But being in the Arctic all stations were South including the fellow I used to work in the Antarctic hi hi.

However, an un terminated horizontal loop resonant at 160 or 80 mtr bands works very well (and efficiently) on harmonic amateur bands. You are correct that it almost never works (loads) 100% on all frequencies on all bands, especially even multiples, with a given height and feed line/tuner combination. With a little tinkering all bands/frequencies of choice are usually not too difficult to achieve.

One of the problems/advantages of 'TRUE' multi band terminated antennas is the added directional properties.

Just as an aside, many years ago, there was a company that marketed a 'multi-band' coupling device for dipoles (they advertised in QST magazine). Their device was finally exposed to be a simple resistive (dummy load) with 2 external connections for the dipole hi hi. Users swore by them !! There are terminated antennas and then there are TERMINATED antennas hi hi.

There might also be a difference if it were fed with coax, or otherwise not nicely balanced, so that the feedline becomes a second radiating structure.

Jim,

I'm not sure what kind of power the antenna would take at the even multiple frequencies. Sure, you could get it to load (possibly) with a tuner but most of the power would go heating the components of your tuner (instead of the resistor) not to mention the RF dancing around everywhere!

If I were to build a full wave loop for 160, I would probably make it horizontal and feed it with coax vs ladder (like the WH2T, AKA skyhook in the ARRL Handbook) The feed point is going to be somewhere around 100 ohms, or a 2:1 VSWR at that frequency. It should also load well on the odd order frequencies with a tuner.

Here's another idea, you could combine two loops with one feed. Have a 160 and 80 meter loop connected to the same feed point and suspend them the same way. That should take care of the even/odd - voltage/current feed problems. I've never tried it but I think it would work up through 10 meters.

I don't think so .... there would be no difference from the point of view of the impedance of the antenna as seen by the coax. You are correct in that direct connection of coax would allow antenna current to appear on the outside of the coax shield (in effect creating another element from the feed point to ground). This vertical radiation would interact with the antenna radiation causing a distortion of the normal horizontal loop radiation (not always undesirable). However, the characteristics of the feed line radiation would not change by reversing the connection at the feed point.

I know that signals from a bidirectional loop (vertically oriented) can be mixed with signals from a near by vertical antenna (sense antenna) to provide a means of detecting which is the true direction of the station being nulled. I may be wrong, but I don't believe the connection at the loop will change the relationship with the sense antenna.

Jim

>(instead of the resistor) not to mention the RF dancing around everywhere!

You are exactly making the point ... the problem in feeding a loop (or a dipole for that matter) on even harmonics is not that they won't work ..... but that the voltages produced make it difficult to use high power ... by high power I mean 100w or more. It is much easier to tame the feed point impedance if the tuner can be located right at the feed point. Otherwise great care is required to dress the feed/tuning system to avoid damage to components. The damage is due to high voltage, not power consumption. If you find the best combination, provide a good tuner, and operate with reasonable power the antenna system is efficient but always in danger of burning at 'key points'. An antenna system might be quite efficient and easily fed at QRP level of power, touchy at 100W, and all but impossible at 1000W.

You have the same problem trying to feed a 'short' antenna ... eg. feeding a 20m dipole on 40m. Putting in tuning stubs will linear load the 20m dipole and it works great on 40m ... but then it is difficult to feed it on 20m as it becomes a full wave dipole !! you can't win hi hi. But it is possible and it also makes an excellent antenna ... with the same feed proviso's. e.g. high voltage dangers. However, putting an automatic antenna tuner at the feed point eliminates the problem and a 20m dipole works great on 40m ... even without the linear loading stubs. A simple relay switch at the feed point that switches the stubs in and out of the circuit turns the 20m dipole into an excellent 40m antenna.

I have also used your other suggestion .... using concentric loops or parallel dipoles on the same feed line ... I guess the perfect 'everything' antenna just doesn't exist hi hi.

Isn't that the truth. When I had my "big" yard I solved the problem with an antenna for every band, but alas, I've lost my yard and I'm down to a 104' wire for listening only. :(

Hi Chris.

I am back from a 2 weeks business trip and i am taking a look at the push-pull amplifier schematic.
Tell me that this amplifier run on 12V, because there is no value assigne to the Vcc . I would like to use it with my mobile setup that run on 12V .

Thanks again .

Gillis

forgot to mention i am using a Kenwood 570d for this loop. 100ws wont
have an amp for awhile if I get 1 at all. I may be 1 of the lucky 1's
and 100w will work fine and do allot .

and thanks for the replies I have been reading allot more today . the
resistor idea was nice and will be looked at after install. if it dont
work so good without 1 Its a good thing to try ..thanks !!

I will go with an 80m and work from there I don't have 500+feet to
install a 160m so why push my luck.

Unless somebody can recommend a different all band antenna I still
think the loop be my best bet for my lot and radio. I also have tuner
in radio. it would be great if I can use it alone and not the MFJ tuner.
I am not really happy with MFJ tumer but its what I could afford at
this point.
now next ?? is a balun for the antenna to go from 450 ladderline to
rg-213 ?/ will 1 be needed. the coax will be just maybe max 10 feet if
that long to go from window to radio or the ladderline will come all
the way to tuner and then to radio . use the built in balun.
I am concerned with heat also as a few have mentioned already.
would you recommend a seperate balun and not use the 1 inside tuner.
(it dont look all that great of balun.)

thanks for the suggestions and ideas. we will know more in 2 weeks
after I move into the house. its 500 mile trip to house so it be a few
weeks maybe before loop goes online but it will be online. can always
make it into a longwire later if needed.

Fred,

Build the loop at a full wave and feed it from the tuner with a 50 ohm coax. RG-213 is very good or RG-58 if your only running a 100 watts. Forget the balun and ladder line. If you want to use a balun, use a 1:1 at the feed point of the loop.

forgot to mention i am using a Kenwood 570d for this loop. 100ws wont
have an amp for awhile if I get 1 at all. I may be 1 of the lucky 1's
and 100w will work fine and do allot .

and thanks for the replies I have been reading allot more today . the
resistor idea was nice and will be looked at after install. if it dont
work so good without 1 Its a good thing to try ..thanks !!

I will go with an 80m and work from there I don't have 500+feet to
install a 160m so why push my luck.

Unless somebody can recommend a different all band antenna I still
think the loop be my best bet for my lot and radio. I also have tuner
in radio. it would be great if I can use it alone and not the MFJ tuner.
I am not really happy with MFJ tumer but its what I could afford at
this point.
now next ?? is a balun for the antenna to go from 450 ladderline to
rg-213 ?/ will 1 be needed. the coax will be just maybe max 10 feet if
that long to go from window to radio or the ladderline will come all
the way to tuner and then to radio . use the built in balun.
I am concerned with heat also as a few have mentioned already.
would you recommend a seperate balun and not use the 1 inside tuner.
(it dont look all that great of balun.)

thanks for the suggestions and ideas. we will know more in 2 weeks
after I move into the house. its 500 mile trip to house so it be a few
weeks maybe before loop goes online but it will be online. can always
make it into a longwire later if needed.

Barry....Your loop list email just went into the bulk file. I am having increasing difficulties with this on all my yahoo accounts, with both person to person email and yahoogroups. Many important emails go to the bulk and I don't see them for days later. Many recipients never get my emails. Does anyone know the cause of this? For Barry's email is it perhaps because he has "bank" in his last name? Is that a key word that indicates to yahoo that it may be a fraudlent email? If so, that's ridiculous, because it means that if my bank or credit card company emails me something PER MY REQUEST, than I'll never get it. What causes these sorts of problems and why do they seem to be increasing, is it part of yahoo groups's war on spam? It would seem that Yahoo-Groups would want its members to receive all of the messages...and not throw them into the bulk folder...
Anyway, whatever... -Tom

I'm sure the actual rules are quite complicated. I know one thing they do examine is the ratio of new lines to quoted lines. If there's a big quote with just a couple new lines, for some reason they think that's suspicious and will mark it as spam. It doesn't happen all the time, but I've heard it can be an issue.

I use Gmail and it will occasionally put something completely innocuous in the spam folder. Fortunately, it looks like I've finally got it trained fairly well. I haven't had to move anything out of spam in a couple months.

Interesting! That may explain why people on
CRAIGS LIST rarely respond to me. I quote the
entire CRAIGS LIST entry on my email, some of
which can be quite lengthy, and then write at the
top, "Hi! I'm interested in that apartment,
radio, or whatever....give me a call at this
number...."

And, it does seem that in the spam folder there
are a lot of messages with words pertaining to
financial, banking, vacation, travel, lifestyle,
products for human pleasure, etc.
This, to me, seems like a "violation" (well,
sort-of) of Freedom of Speech. I don't mind
getting advertising, even if it is unacceptable
or potentially offensive. I just delete it,
unread. That's one issue I'm a Libertarian on.
HA HA HA HA

-Tom the unpredictable self-thinking
contrarian...

And, following what you said I deleted most of yr
post...

Hi Tom,

Well I never heard of a 2 way spam filter hi hi. Most internet service providers ISP's provide spam filters that use various algorithms to filter out unwanted mail (in coming). They all provide an 'off-on' switch and usually a variable filter adjustment .... eg ... from filter only messages containing !@#$% to non get through. In addition they usually (ISP's) carry virus detection as well (a good thing). This explains why a lot of your incoming mail ends up in the 'bulk' file. However I don't think your ISP also filters the outgoing mail !! At least I am not aware of that kind of feature.

To solve the problem of your incoming mail going to 'bulk' simply turn down or turn off your ISP spam control. In my case I use only the first (lowest) filter setting. I check the 'bulk' file from time to time to make sure nothing good gets stopped. As a result my in box always has a few unwanted messages (i never open anything I don't recognize) which I delete.

However, if your outgoing mail never gets anywhere .... I would say that is an ethereal problem .... best dealt with by a Shaman. Hi Hi

Jim

5273. Live In Apartment Need Help With LW Reception

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-05-17 02:20:42 UTC
From: Adam E.
Topic: 5273 Message: 5273

Hi,

I need help with improving long wave reception indoors in my
apartment. I built a loop antenna, but I need some kind of tunable
amplifier that will receive a signal and also be tuned for better
reception. Is there a circuit out there for a tunable preamp for to
connect 2 leads of the loop antenna and then connect the amp circuit
to the radio receiver which is a Grundig G5 receiver. If there are
transformers and inductors
involved in the circuit please help find out where to obtain them.

Thanks,

Adam E.

Hi Adam,

Wouldn't it be easier and more effective to tune the loop? Not sure what kind of increased performance you require ... eg. increased gain ... or selectivity to decrease adjacent signals. A tuned loop provides both increased signal and selectivity. If you are using an untuned loop and your receiver needs added gain and selectivity, you can provide your own high Q tuned input circuit. Most commercial tuned RF amplifiers operate MW and SW.

Jim

This site has a high gain preamp that works with loops or wire antennas and is tunable. A mechanical variable cap can be used instead of the varactors, if that's easier obtained.
http://www.mlecmn.net/~lyle/preamp/preamp.htm

Too bad you're severely handicapping yourself for trying to receive LF--indoor antenna, and basic portable receiver. The Grundig E1 would be a much better LF receiver for you, if you have to be content with using a portable radio.
Good luck!
Steve

Topic: 5250 Message: 5276

> I don't think so .... there would be no difference from the point of view
> of the impedance of the antenna as seen by the coax. ...

I didn't think we were talking about the impedance of the antenna. I thought we were discussing whether reversing the connections would change how the antenna works (i.e., its radiation pattern, and/or effectiveness in certain directions).

My reasoning was, if the feedline is nicely balanced, and the loop is also nicely balanced, then swapping connections shouldn't change anything. But make the feedline a radiator too, then swapping connections changes the relative polarity of the feedline and loop components to the total radiated signal.

> I know that signals from a bidirectional loop (vertically oriented) can be

Wouldn't swapping the loop's leads flip its polarity (relative to the vertical sense antenna), thus causing signals to cancel where they had added, and vice-versa?

Andy

5277. Wellbrook loops

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-05-20 09:20:55 UTC
From: Dominique Kremp
Topic: 5277 Message: 5277

Hi all,
Did anybody ever test various wire thicknesses to do the Wellbrook loops (AL100 / AL100M)?
It seems that the loop wire has to be thick enough to be less inductive.
I've been told that 16/02 minimum is recommended, 32/02 (32 strands X 0.2mm / 3kW/220V kettle wire) could be better.
Does it make a significant difference, does it improve the signals ?
My loops (AL100/AL100M) work fine so far with a 0.95mm wire.
Thanks for any reply

Dominique

Could reversing the connection of the feed line to the loop affect which ray is intercepted stronger, the ordinary or the extra ordinary ray. I don't think wether a balanced or unbalanced feed is used is as important as the polarity of the feed. Typically for NVI sounding, when using loop antennas, the feeds are reversed to determine which way will provide the most usable returns.

Sorry, ... i mentioned impedance as it has an effect on some aspects of performance .... albeit not much in relation to radiation patter (one aspect of performance).

Feeding the balanced antenna with an unbalanced coax feed line will indeed introduce a second source of RF (looking at it from the point of view of a receiving antenna). They mix in some way and present at the input to the receiver. Reversing the connection might affect how they mix. But, the horizontal loop and the vertical feed line would both be omni-directional which wouldn't produce a directional pattern. If the loop was vertical then it would have a bi-directional pattern .... the basic requirement in order for the sense antenna to be useful. The mixing of the signal from the omni-directional sense antenna with the bidirectional loop can produce a heart shaped pattern (a broad signal front with a sharp null). The RF sources must be mixed in equal amounts to produce this pattern.

I assume reversing the loop signal will flip the null to the opposite direction. The key is that the loop is already bi-directional.

Jim

¡ Hola, Dominique !

Would you like to tell something about the measures of your Loops?
xcm x ycm, where and how high, towards which directions or even turnable?

As you may have already seen from my emails (?), I have tested The Wellbrook ALA 100M only in my radio-room with three different size coaxial-loops... I tried to purchase a rotor, but haven't received it yet.
I also connected my Wellbrook ALA 100M Amplifier with my 82 cm diameter Hula-Hoop-Loop with three turns of enamelled 0,5 mm wire, and it worked rather well, so it doesn't obviously matter much, if one can't use a larger Loop with it. - I am going to do more tests wit my copper-tube loops later, when time allows... You see, testing is my main business in my radio-hobby... I get a lot of pleasure seeing and hearing results of my "work", especially now, having received my CA-6243 Capacitance/Inductance Meter from Hong Kong.
Nice to be able to know more exactly the measures of Coils and Capacitors. Next I want to get my hands on an Antenna Analizer.

Best Regards from Ami.

One thing about LW reception is the radio. The Ten Tec RX320(D) is intentionally detuned below 1000khz to avoid issues with interference from strong AM BCB stations and emphasise HF 3-30mhz. The fix is easy to bypass the BCB filter on the RX320, but just be aware some radios just are not cut out to go to LW.

Sorry it got way too long, but if you don't want to read just skip to links and link notes: (experts please feel free to correct me and teach me.) Also this info is worth what you paid for it? Ha-ha.

I'm no loop expert, but being in a somewhat similar position, may be a little ahead of you, I have done some research into this, some suggestions and opinion follow. I included a lot of links which might be of some help and informational. Again I'm no expert but plan on doing more loop experimentation.

Just to make sure we'er on the some page: "long wave radio band is the range of frequencies approximately lying between 12 and 1000 kHz".

http://en.wikipedia.org/wiki/Longwave

Do you really want to listen to anything below 500khz? 200khz? I know some LW BC stations go to 153khz, but I'm not too interested in them. In my opinion freqs below 200khz, antenna wise and radio signals, starts to be am issue. Lets face it, LW stations have antennas that are pushing 1/4 miles long. Some ULF mil stations have mile long antennas. Now you want to have an antenna to receive this, it should also be long. LOOP to the rescue, but it will involve lots O wire and or some kind of fancy tuner/amp. There solution is somewhat expensive commercial solutions or home-brews. Most of the info is on "The Google". I have included some of my favorite links below.

You can build a nice 2'x 2' or 3'x 3' box loop. Take a 3'x 3' box and 8 turns about 100 feet of wire. That gets you gets you all of BCB (MW) to the bottom of HF, a nice band range from 475khz to 2945khz. You can pick off half the loops (4 turns) and go up to about 5900 khz. This does NOT help with LW, so what to do?

If you want to get down to 200 khz its going to take about 20-25 turns and lots of wire, about 200-240ft of wire. That can get you down to 200khz. 400ft gets you to 120khz. Your LW loop will only have a top end of about 1000khz. I would make it so you can pick off the number of loops like the above BC band loop, to get higher freqs, at least to 1.8Mhz MW would be nice. Making specialized antennas for a narrow band is a valid thing to do. You can't have enough antennas! ha-ha

I personally haven't found lots a love down there below MW, in program content or signals. It's part it's no doubt my antenna and my lack of effort hunting in LW, but I know people love to listen to beacons, some military stuff and apparently BC stations. Working down below BCB can be a challenge I understand. With the fact you require

an INDOOR antenna you are starting at a disadvantage. Their antenna (LW broadcasters) have LONG wire antennas outdoors for a reason. Right? 200khz transmitters use antennas about 1/4 mile long. Ouch! Those ULF military stations have mile long antennas!

Can any one tell me the charm of LW and why its interesting? I like the technical challenge and DX bragging rights, but content wise what is there?

As you know there are all kinds of loops you can build with & without pre-amps (just google it). As some one said, why not tune your loop? You can do that with different pick-offs along the loop and of course an air capacitor to make it all resonate at the proper freq.

For you LF/LW desires, it takes lots of loop (wire). (See below)

Tricks and smoke-N-mirrors are fine, but there's nothing like a long, long wire, outside and high up. (Sorry I know blasheim on the LOOP group, ha-ha). I have 1000' of 22awg tefl stranded wire. I'm going to go out somewhere in the country and lay that baby out along some trees, connect to my Degen DE1103 portable and see what it gets. The DE1103 can tune to 100khz.

****
LOOPS LOOPS LOOPS LOOPS

There are the commercial loop units (antenna, tuners), Wellbrook and MFJ. I'm in the market for a loop to play with, learn with. I am thinking of a DIY homebrew or commercial first.

I have a small house on a small lot with homeowner rules, so out-door antennas are marginal, both physically and per HOA rules. So far no one has noticed my +45' random wire (small 22awg white wire) from house to tree. I have got good use out of the outside wire (almost 9000 mile QSL's in the 25-49m band).

An outdoor antenna is almost always better than one inside. The higher and longer (more turns) the better for LW/LF, right. No matter what you do the truth is you can't make up entirely for your in-door limitations, usually. If you had an attic, sometimes that works well. If the HOA gets snippy, that is where my antenna must go.

You say you have a loop and want to know how to tune it? If you built it with an air capacitor you can tune it. There are a 100's of loop plans and calculators on Google to "tune" the freq range you desire: size, number of turns and capacitor range.

**** COMMERCIAL LOOPS ****
Here are some commercial loops & tuners that might work for you.

Wellbrook:
http://www.wellbrook.uk.com/products.html#LA5030

Noter: ALA5030 or ALA100M? The ALA100M is what you might want. You provide the wire and the unit is a tuner and amp. The ALA100M is 138uk, so that is almost double USD. Bummer. However the ALA100M sounds like a good unit, RX only amp loop tuner, indoor, supply your own wire.

MFJ has loop tuners; Here's the link
http://www.mfjenterprises.com

Note: Click on antenna tuner and look at MFJ-932 and MFJ-933 (my pick), MFJ-935B. Why do I suggest them. They are for RX as well as TX'ing. I assume you might want to CQ someday. Even not, you can always sell it. You supply the wire and simple PVC support (or drape around book case or window. You can select different loop sizes (wire length) to optimize freq. Last you might want to listen to higher freqs some day? Simple, just hook-up a longer wire loop. eHam.net has reviews of these antennas and tuners. Mixed reviews but they work pretty good I am told.

**** HOMEBREW ****
For homebrew, which I am thinking of, DX only outdoor active magnetic Loop. It looks like an attractive antenna. The antenna police might think its for satellite TV which is allowed. If not it will go in the attic, but with a big heat furnace/AC evaporator it will not work as well as outside above the roof line. I can hide the rotor and just have the loop above the roof line. Here are some plans for DIY amplified magnetic loop, as follows:

My favorite
http://www.techlib.com/electronics/antennas.html (My favorite)

http://www.eham.net/articles/18699

http://www.mlecmn.net/~lyle/bal-pre/bal-pre.htm

http://users.tpg.com.au/users/ldbutler/Loop18MHz.htm

http://www.vlf.it/easyloop/_easyloop.htm

Note: My experience with amplification (mostly whips) is it amplifies the signal and the noise equally. Of course the joy of loops is noise rejection off the null sides. If you have no local noise situation (rare) an amplifier might be great, but if you had no local RFI noise and a good passive antenna, you would NOT need an antenna amp.

Bottom line there's no magic, simple solution or getting around the physics of a good basic (passive) antenna loop, wire, dipole, monopole or beam. However a passive or active tuner/amp can do wonders but adds more stuff and need to tune it for each freq. Again if you target one freq fine, but I like to scan over the bands (HF). Antenna tuning would be a pain but a neccassry evil sometimes.

Never the less, I want to play with some amplified/tuned loops? My first will probably be a 3'x3' passive loop as shown below, a passive

MW/LW loop with multi wraps (about 200' - 240' of wire) around a
3'x3' frame with an air capacitor. You can wire them so they have
coxial feed-line.

http://www.i1wqrlinkradio.com/antype/ch13/chiave1456.htm
(ton of loop links at bottom)

It would be nice to have a loop to target known signals. For scanning
a loop is a bit of a pain. I'm thinking of mounting the loop in the
attic. A servo is used to tune the capacitor like RC servo, electric
drill or motorized volume control. Put it in the attic with a rotor
and remote tune capacitor; heck with the antenna police. One thing
about a LOOP is having it in the middle of the room. They look like
art to me, but the wife might not like it.

Some more LINKS: Here is a AM BCB loop kit/plans:
http://www.mtmscientific.com/loop.html

http://www.mindspring.com/~loop_antenna/
(ton of loop links at bottom)

Cheers George

Thanks for the information, I really appreciate it. I guess I a
loop antenna will be my best bet still. I have used longwire antennas
in the backyard at my old house, but since I don't have room for
longwires for longwave a loop will just do. I will be looking out
for schematics and drawings for longwave loops here when they become
available. Thanks Have a good day.

Hi, I have been a member here since 2005, I have been participating in this group for a long time. This group is better than the ones that others created and there are over 2000 members. You will alot of information about loops here and also you can get parts from stormwise and other places to build your loop antennas. I am in a apartment now experimenting with loop antennas and I am doing my best to keep the antennas near the window as best as I can. When I get variable tuning capacitors I am going to reactivate my loop antenna that measures 8ohms to receive broadcast band stations from Europe on LW.

We wish you the best in your DX.

Welcome here.

Adam E.

Dear Adam,

I built a loop for the longwave band. It goes from below 150 kHz to 650 kHz. Please look at http://ph.groups.yahoo.com/group/loopantennas/photos/view/5021?b=8 for a photo and http://groups.yahoo.com/group/loopantennas/message/5145 for a short description. You will need a lot of wire, a BIG variable capacitor and a lot of wood for the construction, but it works good. The loop will be coupled inductively to the receiver as shown on the picture.

Good Luck!
Heinz

Hello Heinz,
Im live in Brazil, I construct an antenna to wave with 86 cm long each side, using 50 laps of wire, making a total of approximately 170 meters, and used a capacitor of 40 to 365 pf, because I have another of greater value, but the result was great . Congratulations on construction and finishing.
Respectfully,

Eduardo

Hugh, I would have answered sooner but have been away for awhile.
The black box is fitted with an so-239, the coax runs up to a
lightning arrestor at the shed peak and grounded right at the base.
The coax runs about 90 feet to a 3-way Diamond antenna switch. My MW.
G5RV and AOR SA-7000 are then fed thru an antenna tuner. The MW
antenna is then fed thru a 10:1 balun and then into my Icom R75.
Also in the pictures you see part of my G5RV fed to 65 feet of ladder
line and then into a 140 ft coax. Ed Dawson

How about putting a large grounded aluminium or copper sheet near the other end of the small directive antenna trying to prevent the antenna to receive signals coming from the non-wished direction?
Has anyone tried it?
If not, that will be my next test/experiment...
TV antennas and Yagis are made in the same principle, aren't they?
Ami

Andy <Andy.groups@...> wrote:
> I don't think so .... there would be no difference from the point of view

I didn't think we were talking about the impedance of the antenna. I thought we were discussing whether reversing the connections would change how the antenna works (i.e., its radiation pattern, and/or effectiveness in certain directions).

My reasoning was, if the feedline is nicely balanced, and the loop is also nicely balanced, then swapping connections shouldn't change anything. But make the feedline a radiator too, then swapping connections changes the relative polarity of the feedline and loop components to the total radiated signal.

Wouldn't swapping the loop's leads flip its polarity (relative to the vertical sense antenna), thus causing signals to cancel where they had added, and vice-versa?

Andy

I need a loop that has increased gain and selectivity. And can have
an amplifier for more gain. But I still need to learn on how to make
a signal magnet (magnetic loop that ignores electric fields) cause
there is noise present in the apartment area such as nearby TV's and
computer noise signals, and cable TV noise. If you can help me find a
circuit for me to study and also are there any books on this? I have
some books on JJ Carrs receiving antenna book, but do not have a copy
of JJ Carrs Loop Antenna Handbook. And 2 different volumes of Radio
Science Observing 1 and 2, but the 2 books were hard to understand for

intermediate hobby in electronics. I just hope the parts are still available to buy to build these loop projects.

Hello Castello and Heinz
This is off topic, but fun.
I live in Australia which changed from imperial measurement to metric in 1966. We have become bilingual and usually at ease with either system. ... Now I am a farmer and not so long ago bought a new tractor.. It is a Massey Ferguson (English marque) made in Brazil (Brazil is Metric is it not Castello?) but everything on this tractor is old fashioned imperial. I think I am comfused! Now if someone could suggest some dimensions for this loop I am contemplating in Cubits, or the speed of light in Furlongs per Fortnight my day will be made. Cheers ... Hugh

5297. Building a Loop for Wellbrook ALA 100 M

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-05-26 22:42:17 UTC
From: aimo ruoho
Topic: 5297 Message: 5297

Hello, folks!

I would like to build a turnable Loop for use with my W.ALA 100 M Active Antenna Amplifier. I would turn it with a proper rotor. (Any ideas of good new rotors to be bought from Europe?)

I have been calculating some possible measures for this future Loop.
A: 8 meter, 4 x 2000 mm of thick plastic coated wire, diamond shape, cross lengths 2825 mm or circular shape, 2500 mm diameter.

B: 7 meter, 4 x 1750 mm of thick plastic coated stranded wire, diamond shape, cross lengths 2470 mm or circular shape, 2200 mm diameter.

C: 5,4 meter wire, 4 x 1350 mm plastic coated stranded, diamond shape, cross frame lengths 1900 mm or circular shaped, 1600 mm diameter (1,6 meter or 160 cm).

If you would choose, which one of these would be the best according to your opinion?
But perhaps you have better ideas?

I already have enough of wooden lists of 1900 x 40 x 12 mm, so I would like to use them to build a wooden cross-formed frame, but before I begin building, I would like to read your very much appreciated expertice, I also possess long PVC-tubes to go that way, if I prefer it, but I'd like to have there also very good advice, if available from group members.

Best Regards from,

Ami

Thanks a lot, Trevor !

It really was a very nice gift from you and really interesting.
I was just building a 6' 4" x 6' 4" cross framed loop with 1 turn = abt 18' wire.
I'll connect it later with my 100 M...
Perhaps I should have used more turns? Maybe I'll do it some day.
7 to 8 meters (21 to 24 feet may be better) ?
This M-model will work with 1/2 of the 100-only-model wire length.

Thanks again and best regards from Ami.

Yes!

I chose the "C"-version. It gives a decent signal on LW, MW and tropical frequencies + SW. Lots of strength. I put it on the upper roof of my house without anything but the roof ground!
Waiting eagerly to raise it a few meters above it and having a rotor to turn it around... A lot better than the loops in my room. But to be truthful, it doesn't beat my DX 1 Pro MK II, at least yet.

Best from Ami, an optimist homebrewer.

5304. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-06-01 22:49:31 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 5304

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

Changing the feed point will impact pattern. Changing or swapping the
the leads shouldn't, since the signal we're dealing with is
Alternating Current not Direct Current.

At 10:47 PM 6/3/2008 +0000, you wrote:

>Changing the feed point will impact pattern.

I believe the original post referred to a horizontal loop. Why would
placing the feed point impact pattern?

> Changing or swapping the
>the leads shouldn't, since the signal we're dealing with is
>Alternating Current not Direct Current.

Wayne C.

I don't think anyone was trying to radiate with DC hi hi. The issue is
that feeding the horizontal loop with a coax feed line will introduce a
vertical component (antenna current on the outside of the shield). Will
the interaction of the two radiation components change if the feed point
connection is reversed? The idea being that the vertical portion would act
like a 'sense' antenna.

My sense (no pun intended) is that a 'sense' antenna works with a
bi-directional (vertically positioned) loop and not with an
omni-directional horizontal loop. The combination of a bi-directional loop
pattern with an omni directional pattern of a vertical antenna will produce
a heart shaped pattern .... (used in direction finding).

I feel there is a possible affect in pattern if the loop is oriented
vertically and not if it is oriented horizontally. For full effect the
signals should be mixed with relatively equal strength. In a system where
signals from a bidirectional and omni directional antennas are mixed the
null (top of the heart pattern) is indeed swapped (by 180 degrees) when the
feed point of the bidirectional antenna is swapped. It would only be by
chance that the two signals in a coax fed large loop would be of such
relative strength that any noticeable pattern change would occur.

Actually, I think it can. For example, a large horizontal loop used above its primary (1-wavelength circumference) resonant frequency has lobes and nulls in its pattern, and moving the feed point would rotate that pattern.

With a square or triangular loop there is also some difference between feeding it at a corner or the middle of a side.

> I don't think anyone was trying to radiate with DC hi hi. The issue is

Personally, I wouldn't have used the term 'sense' antenna, but if it works for you, OK. The point is there are two radiators present, the loop and the feedline, and the total radiation (when used for TX) or reception (for RX) is the sum of the two, which might add or cancel to varying degrees in different directions.

> My sense (no pun intended) is that a 'sense' antenna works with a
> bi-directional (vertically positioned) loop and not with an
> omni-directional horizontal loop.

Although a 'sense' antenna might be designed for use with a bi-directional loop to make it cardioid, it will still to do the same kind of alteration to any antenna regardless of its construction or orientation, even though it might not turn it into a nice cardioid. Both antennas, the horizontal loop and the vertical coax, radiate in 3 dimensions and their signals will add in some directions and subtract in others.

You might not get deep nulls that result when the component amplitudes are exactly equal, but it will be different than having the loop alone.

Then, if you flip the connections at the coax/loop connection point, what was additive becomes subtractive and vice-versa. So swapping the connections there (which was the original question), would change the resulting pattern.

Andy

Jay,
Best Buy will discount in increments so the one for $90 may go down to $43. The on-line is still listed as $199.

I heard my first AM HD tonight, ever. Very impressive - the Legendary Larry Van Nuys on Newsradio 1070 KNX L.A. sounded great. Sounds like listening to streaming CBS talk stations (CBS has very high quality streaming like KNX and KPTK/Seattle and KXNT/Vegas).

HOWEVER ... I'm 460 miles ENE of L.A. and the HD signal is there sometimes, but most of the time, the HD indicator is flashing and not solid.

How does one make an HD antenna for AM, and for FM? They're on the Best Buy web site (link Below) Are there any engineering principles different than a stand My Radio Shack AM 9" loop Terk clone doesn't help in combo with the 5" square loop antennas provided with the Sony HD.

best buy HD on sale $43

You need special solid gold Litz wire wound in a spiral, diamond-shaped loop of at least two feet point-to-point diameter. The loop is tuned with an air variable flux capacitor. This is for AM, of course. ;-)

Seriously, it's just a radio signal like any other. Where you might benefit from a special antenna is if you normally use an AM loop that has a very tight peak frequency. The HD signal starts outside the normal envelope of the analog signal. Based on what my ears have heard (as opposed to what the spec says), the HD signal starts about 5kHz from the carrier and goes to at least 15kHz from the carrier. If your tuned antenna results in significant signal strength drop off 8kHz away from the center of the tuned segment you'll be getting far less of the HD signal and may not be able to lock on any but the strongest.

With an untuned loop you shouldn't have this issue.

Skywave reception of HD is going to be spotty under any but the best of conditions. You will probably continue to get the type of reception you reported from distant stations at night.

The companion HD antennas are on eBay for about $90 with shipping.

I'll run over and see if my local Best Buy has one for under $50.
I'll give it a shot if they do. Gosh those radios sure are ugly! Hope
they sound better than they look.

I've tried a Twin Coil Ferrite loop, a Terk loop and a 100' long wire and it doesn't seem to make much difference what is used on the Sony SDR-S3HD. Even when distant signals are strong it's hard to keep a lock for anything more than a few minuets. The signal is almost 40khZ wide and phase shifting of a signal that wide at such low frequencies makes locking the signal almost impossible. In other words it's the ionosphere distoring the signal enough to keep the radio from locking.

Thanks for the alert to the potential sale price for this radio. Apparently it is a local market thing and varies from store to store. I took a ride over to one of the local Best Buy stores in my area and saw that they had discounted it to 116 bucks. After telling me what a great deal this was, I mentioned that it was on sale for 43 bucks in some markets, then I asked him why the box was covered with so much dust. He admitted that they were not exactly jumping off the shelf. I offered them 50 bucks for it and they came back with 75 bucks. So... I grabbed it for 75 bucks and whipped out an old Best Buy gift card for 50 bucks and got it for 25 bucks out of my own pocket. So, it appears that each store will wheel and deal a little to get these things off their shelves.

As far as the radio goes, aside from a few little quirky things (no battery backup so you lose time/alarm settings and your station presets if power is lost) this is a fabulous radio. I have not used any other antennas yet except for the supplied AM loop and the FM dipole, but had no problem filling up the FM presets (20 of them) with HD content, and was able to receive the two AM stations (one of them in HD)I am apt to listen to without any problems at all. The fidelity is outstanding and the remote is very convenient for getting into menus with a single button press. This is a seriously nice chunk of radio for 100 bucks or less. As a bonus, it has a line input for my little MP3 player and it does a great job with that function. If you are interested in this thing, I'd suggest you read the reviews online at the Best Buy site to get some insight into how purchasers rate it.

I think I really like this thing! Can't wait to plug one of my loops into it for some AM DX work!

:O)

Rob

In a quest to actually hook antennas up to my mini stereo's, which mostly does duty for TV and CD's, I came up with these cheap deals that work. I did not want to go out and buy a $100 worth of indoor antenna stuff I could make which work as well. If I was going to buy an antenna a directional beam on a rotor would be in order. However there is no need, since I live in a target rich radio environment to go with a big antenna. However not wanting to destroy the decor too much here is what I came up with:

http://img249.imageshack.us/img249/7051/amfmslide1pk6.jpg

http://img517.imageshack.us/img517/8027/amfnslide2yo2.jpg

** AM shipping box loop **
The AM antenna is my version of the "Ultimate AM Antenna ** Carver Corporation of Lynnwood, Washington once had plans for with their super high fidelity TX-11b receiver gear back in the 80's.

Here are the plans and excellent analysis of this loop from the web.

Plans "Ultimate AM radio LOOP"
http://members.cox.net/rwagoner/columns/am_antenna.html

Basically it's an un-tuned loop 12" per side. The USPS box is 12 x 13.625 by 3 thick. I had about 23 feet of 22awg stranded tfe lying around so why not. My first attempt before the loop was to string the wire up along the wall horizontal. I did not use a ground and just attached the one end to the radio; it was a noise collector, horrible.

This loop works perfect and that wall is east-west. The main stations are to the east.

I can just tack the box to the wall behind the radio or dresser, out of the way and out of sight. I could even get a nicer box and put a picture on it? ha-ha

There are only one or two AM stations worth listening to, and both are pointed E. A few stations are N-S orientation and fixing the loop N-S makes them go bye bye, which is OK. With out the LOOP I have zero.

Explanation of how and why it works
http://www.midnightscience.com/_web/000003be.htm

Of course there are better loops, tuned with air capacitors and of course larger the better. I went with 5 wraps or about 21.5 feet to get around the box 5 times since it was 12" x 13.625".

64" folded dipole:
The FM antenna is 128 inches of 22awg stranded tfe covered wire to a TV balun/transformer (300ohm,:75ohm) to some 75 ohm TV coaxial, than to the radios spring loaded wire terminals. I used clear push tacks to hold it all up, I soldiered on a little pig tail to the shield at the radio end, which is slim pickings on el-cheap-O coaxial with foil and a few drain wires. It works well I get +25 stations. A hand full are 55-65 miles away. Most of those fringe stations come in 4/5 with some static, but one station has no at all static. There other closer stations with some static, but they are college low power deals. According to radio locate dot com they would be weak signals in my zip. The dipole might not be orientated properly but it's better than nothing. I also went for the low end of the band with 64" overall length. I tried connecting it to the cable TV but that result was poor at best. Just the short coaxial lead to the cable TV splitter was better than connection to cable; for some reason TWC in my area does not superimpose FM onto their signal. Not sure if I was dreaming they could or did that.

The cost to make the loop about $2.00 and it works. Moving it around shows clear gain and noise rejection. The TV or cable box is giving off some wicked 60hz hum and some other noise. The dipole was as cheap. I had the wire, balun and coaxial. Oh I did use crimp on terminals on the wire.

** Carver was famous for building the best amps in the world and also suing audio magazines. He threw down challenges and won. The company is out of consumer products but they still make high end commercial sound systems for theaters under sunfire. Carver still holds a boat load of patents on things like Sonic holography, Magnetic field coil power amplifier, Transfer function modification, Digital Time Lens (DTL) or "Soft eq", Asymmetrical charge coupled stereo detector. The AM tuner of the TX-11a and TX-11b versions employed a notch filter that demonstrated an AM broadcast can exceed the 15 kHz bandwidth of FM stations without objectionable

interference (in theory, but may no longer be true since
about 1990 AM freqs spacing was reduced, I think?)

At 11:51 PM 6/15/2008 +0000, you wrote:

The 'Ultimate AM antenna' is ultimately a compromise given the situation of using the TX-11. The compromise being enough signal for good copy without overload vs broadband (No tuning). I assume that is what you are aiming at with your situation. I do not know what kind of AM front end your mini-stereo possess, but it probably has a tuned ferrite antenna .... with provision for connection of an external antenna. I have a number of quality AM receivers with this kind of front end design. The result is that you in fact have two antennas (both loops) and 2 RF sources. The result is that orienting the shipping box loop for minimum noise is only half the solution; the mini-stereo must also be oriented so it's internal antenna produces a minimum noise. If your mini-HiFi has a plastic case it probably has an internal tuned ferrite antenna.

The 'Ultimate Am antenna' is not a DX antenna (to be fair it was not designed to be). Simply tuning the loop .... even with a smaller diameter than 1'x1' will provide dramatically better performance ... more signal voltage with a narrower pass band. In my location the 'Ultimate AM antenna' falls dramatically short of the mark since the closest AM station is 180 miles away (almost as the crow flies). The result is, for me, all AM reception is DX hi.

Getting back to receivers again, I have several quality receivers that are well shielded with no internal ferrite antenna; no external antenna .... no reception. One of them is an excellent HiFi receiver ... old, but certainly more modern than the TX-11. It has an excellent front end with a tuned RF amplifier. It came with a simple un-tuned loop for AM which consists of 3 turns of insulated wire on an 8.5" plastic loop form. It worked vy well on local broadcast stations (we did have 2 stations a few years ago). In order to pick up the DX stations I constructed a tuned loop about 12" square. I then simply made a suspension hook on the tuned loop on which I place the 8" untuned loop when tuning DX stations. After the last AM station closed down (6 mo ago) all AM reception is DX . The 'Ultimate AM antenna' won't work here hi hi.

By the way, with small loops maximum signal is off the sides and the null is broadside to the loop, opposite of full size loops. I find that rotation is seldom required. The null is quite sharp but maximum signal is quite broad. All that is required is to orient for minimum noise.... thereafter reception is good to acceptable in all directions except for the small portion of the azimuth occupied by the null. However, as pointed out in the online article you posted, tuning the loop for each station is a pain ... unless your objective is DX hi hi.

By the way, I am located in Thunder Bay on Lake Superior. The DX stations
are all in Minnesota and Wisconsin .. I often travel down to Duluth and/or
Minneapolis so I like to keep in touch with their local news hi.
I can sit out on the deck and receive 4 stations with 'full quieting' with
a simple 1 ft tune loop.

If you will go to the photos section on the first page, Loop Kits by tenorman1952, you will see a photo of my "Ultimate AM Loop".

Regarding built in ferrite antennae, these untuned loops work very will with tuners that do not have built in ferrite sticks. In fact, they seem to short out the ferrite stick and the tuner gets less signal.

My untuned loops work very effectively with my various Onkyo receivers and tuners, all of which lack a ferrite stick antenna.

As far as DX, I have, at night, from my home on the La Gulf Coast, listened to WSB in Atlanta to the east, WOAI San Antonio to the west, WBAP in Dallas, KMOX in St. Louis, WLW in Cincinnati, WGN and WLS in Chicago. I can pick these up pretty consistently, with good clear, strong signals.

And no fiddling with a tuning cap.

But a tuned loop does have a stronger signal. Still, this simple untuned loop can work quite well in many cases.

Paul

The manual shows no internal loop stick. I took it apart to fix the CD and tape belts. It just has two wire input for AM. I saw no loop stick. According to the manual it came with, it came with a wire loop, but I have no idea where that is. I bought this new about +10 years ago. I love the little thing sounds great. A lot of the mini systems I hear at best buy sound like crud. Also the case is METAL!

TO BE FAIR I have not given the Awia a good A/B test. I'll have to unplug it and bring it upstairs and really compare it to my other "REAL" radios, a Ten Tec RX320D (45' random) and Degen DE1103, using active AM loop with amplified loop booster stick (next to the internal one).

For AM DX'ing the Awia I suspect is not going to great?I could be wrong. Frankly my "Standard" for AM radio is an old Sony ICF-34 portable with a BIG LOOP stick inside. I know its good sized because I also took it apart, 6" may be 8"? The Sony does OK but digital tuning is the way to go. Analog with an inaccurate dial makes DX'ing and ID'ing stations difficult.

> Getting back to receivers again, I have several
>quality receivers that are well shielded with no

>internal ferrite antenna; no external antenna no
>reception.

I don't know about quality but this AWIA cost big
bucks in the day and it has NO internal loop-stick.
In fact the whole case is metal. No loop no signal
at all!

For fun I am going to get it away from the cable
box/TV which put out some sadly. I just got the
TV, Sony KDL-32M3000 and think it is making
some noise. The antenna is right next to it. Seems
to not affect FM, but AM in the 1000-1700 Khz
range has some real howl in spots. Even the
strongest station has a subtle 60Hz hum (but
bairly).

My real radio shack is up stairs with the "real" radios.
This is just for fun. I do have an old SX780 pioneer
in the living room that I want to get going as well,
but the air capacitor has so much dust in it tuning
it is very unpleasant. The Pioneer does have an attached
real loop stick off the back in a plastic case and a
gimbal mount you can rotate and aim. It is at least 6"
to 10" long. I suspect the Pioneer will be a good AM
radio. I used FM to great affect. Its pure analog of
course but has a huge accurate dial, plus a signal
meter, analog of course.

BTW on the strong stations (680 and 850) moving
the loop N-S brings in normal static and E-W
brings the signal in well. So the loop works to
some extent. I plan on making a nice 2'x2' tuned
loop.

Also I am going to try my Degen/Kaito TG34
active loop on the Awia, again away from the TV.
I'll compare it to my other radios.

Right now the box is behind the radio/stereo and it
works well on the two stations I can get easy and
care about (really one). Frankly a portable AM
radio SONY ICF-34, with a good sized loop stick
(took it apart and eye balled it), doesn't do much
better.

I think in the case of the Awia they put in AM as
an after thought to fill in the features list. It has a 3-
disk CD changer, two auto reverse tape decks,
Karaoke mic input and affects (really works, filters
out voice, re-verb etc). The FM is good but the AM
was an after thought, to fill in the features list. I

love this little unit because it has surround sound;
each speaker has 5 speakers and 4 wires, two sets
of speaker wires, bass and surround. With the EQ
and surround affects it sounds awesome. It even
has an output for a powered subwoofer. I had it
open fix the CD player and Tape deck. Long story
but I fixed both!

Thanks Jim I appreciate all the cool info.

Thanks again.

Yes they do .... however, the point I was making is that if you use an external loop (tuned or untuned) with a receiver that uses an internal Ferrite Loop you have 2 antennas at work. If your objective is to null local noise then the receiver and the external loop have to oriented for minimum noise.

>My untuned loops work very effectively with my various Onkyo receivers
>and tuners, all of which lack a ferrite stick antenna.

Yes, if the receiver does not have an internal ferrite loop antenna then the external antenna (loop or otherwise) is the only antenna. I too use a loop with this kind of receiver.

>As far as DX, I have, at night, from my home on the La Gulf Coast,

For me, receiving stations at night is not DX .... a different kind of DX perhaps. The kind of reception you refer to is 'falling of a log' kind of dx .... any kind of receiver ... antenna or no antenna will work .... never mind if it has a tuning cap hi hi

However daytime reception of a station 250 miles away will certainly require an excellent antenna.

>And no fiddling with a tuning cap.
>
>But a tuned loop does have a stronger signal. Still, this simple
>untuned loop can work quite well in many cases

>Paul
>tenorman1952

So Paul, ur untuned loop will work just fine if all you want to do is listen to local stations during the day and listen random "DX" stations at

night.

I don't mean to burst any bubbles, but I wouldn't consider any of those to be DX. Sure, they're a distance away, but they're all 50kW stations that cover almost half the lower 48. I can get all of those here in Orlando at night on my pocket-sized Sony SRF-59 with the built in 2" ferrite antenna. WFAN and WABC from New York are also regular visitors, along with WJR from Detroit.

I'm not saying your loop isn't good, just that these aren't the receptions to be bragging about if you want the loop to sound good.

I wouldn't go so far as to say there is no DX at night. If you can pull in a 5kW station from 1000 miles away, I'd say that probably qualifies. I agree, though, that hearing a 50kW station from 1000 miles away is no big thing. It's hard not to hear it unless you have nearby stations on the same frequency.

That's good, then your strategy of orienting the external loop is just fine. My HiFi (Nikko) is also metal enclosed with no internal ferrite antenna. With my loop it is the best AM receiver I have ... the problem is that it is stationary indoors hi hi.

I have used a 2' x 2' tuned loop ... again out on the deck .... a marvel to use. Such a loop makes any AM receiver a superstar. It always amazes me when you tune the loop and the radio jumps from 'stone dead' to blaring audio when it resonants on frequency. You would swear someone switched the on/off switch.

Fooling around with tuned/untuned loops is a cheap way to have fun hi hi

Hello all,
I have just joined this group. I have been using a Sony 7600 for several years and have just ordered a Palstar R30CC. Now I'm going to need an antenna. I am thinking of a loop, maybe a Wellbrook. Would anyone care to offer suggestions for primarily AM BCB listening?
Best regards,
Mark Taylor

Hi Mark,

1. Wellbrook 1530 (Model depends on how strong local AM stations are near your QTH; I have the 330S, primarily for SW, but also very good on MW.)

2. Quantum QX Loop v2.0 or v.2.0 Plus+

3. C. Crane Twin Coil Ferrite AM Antenna

4. 100-ft random wire. (Sometimes (rarely) the big wire pulls a better signal than the 220S. Plus, it's fun to make A-B comparisons with the 330S.)

Goot luck.

Bucky

Hi, Jay!

During the day I can also easily pull in a 5,000 w station I like
that is 180 miles away. That is with the untuned Ultimate.

The tuned loop is stronger, but requires more fiddling of course.

Paul

Hi Jay,

You are right, MF DXing at night is a different situation. Trying to receive a particular low power station at night is a matter of dealing with QRM from all the other stations that may be coming in on the same or nearby frequencies. Using the null of the antenna with other special techniques such as signal phasing the DX station can be brought out of the QRM. As I mentioned, my DX is daytime DX ... which is basically a matter of maximizing signals ... and QRM is not a problem.

5333. Re: My wiz bang AM / FM antenna pictures (NEW! Mk V - PB)

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-06-18 03:47:17 UTC
From: gmcjetpilot
Topic: 5321 Message: 5333

The first "box" loop was a "Mk I - SB".
(SB for Shipping Box)

The NEW Wiz bang AM antenna is the "Mk V-
PB", PB for Pizza Box. I call it the "Mk V" for
getting five wraps around the box fairly straight,
despite just eating the pizza, that was in the box
and having two beers (or five). (ha-ha)

http://img443.imageshack.us/img443/2949/pizzabox2cw1.jpg

It works about as good as the shipping box version,
may be a tad less, the wires are closer together and
the frozen pizza box is exactly 12" x 12". The
shipping box was "SB" 12" x 13.625" and wider.
The pizza box is better because it's thinner and fits
behind the dresser easily.

Delusion? (ha-ha) No this is not a great, "ultimate",
wiz-bang antenna, but for my needs to get the
50KW or 10KW stations down the street, it's fine and
better than the wire I was running around the room
that picked up signal but noise like crazy.

I suspect it's as good as the other non-tuned loops
you get with consumer electronics, but no where
near a larger tuned (resonate loop).

Since the two stations (680 & 850) are in the same
direction, close and shooting out gobs of power,
it works. Other wise with no antenna the Aiwa AM
radio gets bupkis. To be honest in 10 years I never
used the AM radio on the stereo.

Now that I have this Mk V - PB antenna, from the
comfort of my bedroom I can listen to Rush
Limbaugh, Shawn Hannity and other shows about,
UFO's, Alien's, Gov conspiracies and how to live
to be 100 years old by eating (or not eating).......?

Oh, may be that is why I never connected the
antenna?

I did "test" the Awia Mini Stereo with a "real"
antenna and against a solid AM radio.

I connected my active wire LOOP antenna to the
Mini Stereo:

http://farm2.static.flickr.com/1266/728763061_2efd16e47d_o.jpg

The above active TG34 loop connected to the Aiwa did
better than Mk V - PB antenna, but not by much. However
when I use that loop on other radios they come alive.
To be fair when you tune the loop the Aiwa did respond
but just not like other radios with loop sticks. There
are two ways to connect, direct or through a loop-stick
booster/repeater.

I used my Sony ICF-34 (cheap portable/table-top
am/fm/tv/wx radio) to compare to the Aiwa mini
stereo with the Pizza box antenna. It was not
impressive, to say the least. The two stations are
50kw and 10kw day transmitters (5kw night), so its
not a technical miracle.

Info on two strong stations from Radio locator:
http://www.radio-locator.com/cgi-bin/info?call=WPTF&service=AM
http://www.radio-locator.com/cgi-bin/info?call=WRBZ&service=AM

The stations are close and the Pizza box behind the
dresser is aimed at the two close stations, mission
accomplished, 50-cent antenna. As I said turning the
Pizza box 90 degrees does cause even these strong
stations to get some static (ie rejecting the signal).

The two strong stations sound excellent on the
Awia, but weak stations where stronger on the
Sony. The Sony also heard stations the Awia could
not, even moving the Mk V -PB antenna around.
The Awia really picked up crazy noise in spots.
Also the location of the 1st floor bedroom, inner
walls is not very ideal. My radio room is 2nd floor
near corner windows.

Still the Sony ICF=34 compared to the Aiwa stereo
just ignored noise, suppressing partly or totally
(better gain, BW, filters?). I had this Sony radio in
the closet (got it free at time-share deal), thinking it
was junk. I'm impressed, it really works (but it's
not a RCA Superadio III I am sure).

If I connected a long-wire to the Aiwa stereo's AM
radio antenna input, would it become a DX
machine? Yea but not a good one I think. It's
digital tuning is locked into 10 Khz steps.

Conclusion, if you want a 'LX' antenna for strong
local stations, the Wiz-bang, ultimate, Mk pizza

box will work. Most of these stereos come with some kind of loop, which probably do as well, but for fun build one and see how it compares. I am sure changing wraps and size you can tune it.

A nice light wood frame, with some varnish would look classy, verses the Pizza box. Of course if you are going to make a loop a 2 foot'er with a air capacitor to "resonate" would be time well spent.

Cheers George

5334. AM ferrite loop for HT?

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-06-23 13:08:22 UTC
From: genedathe
Topic: 5334 Message: 5334

Hello,

Please forgive if this has been covered before.

I'm looking for a MW ferrite loop with a SMA connector to replace the stock rubber duck on my Icom 92AD. One antenna screws off, other one on so I can convert the HT over when the ball game comes on.
Any such beast?

Thank you in advance,

73 de NAØG

Hi Adam,

I assume you are looking at a 'small' loop antenna .... technically a small loop is considered to be 1/10 of a wavelength in dia. or less and it is to be used for SW reception ... eg you are not transmitting with it.

Lets say your SW loop will be for reception only and physically about 3' in diameter or less.

Now such loops fall into 2 categories .... tuned and untuned. Tuned loops are very efficient and work vy well with the shortcoming that they either have to be located close enough to the listening position so you can manually tune them or you contrive a system to tune them remotely if it is to located at a distance. Untuned loops of course don't suffer this problem .... they are however inefficient and require a high gain amplifier to compensate .... the amplifier located at the loop position.

There is a somewhat intermediate solution that uses a tuned loop that is tuned at the end of the feed line by an 'antenna tuner' located at the listening position. However, the distance between the loop and tuner is limited to approximately 8' to 10'

Having said all this, you will have to narrow down your project hi hi

Jim

Adam; I agree with Jim. What do you want to build? ... untuned passive loop? active loop? tuned passive loop? resonant cut loop/folded dipole? 1.5 years ago I did not know anything about loops but I read through some of the 5300 messages in this particular forum & used Google to find loop theory and projects on the web. I learned the difference between active verses passive and tuned verses untuned. What I couldn't understand, people on this forum helped me out. Go figure out what you want to build by doing some reading - or at least do some reading, get totally confused (it happened to me :)- then ask questions on how to proceed and we will jump in and help you out. Or buy a Wellbrook and be done with it :)

Mark

A wideband tuned passive loop will be very difficult to implement as the impedance of the loop will vary significantly. For instance, a 1 meter diameter loop consisting of 1 turn of 1/4" diameter copper tubing will have a resistance of about 0.5 ohms at 4MHz, 10 ohms at 12MHz, and then increases to 420 ohms at 15MHz. It's parallel resonance is around 17.9MHz. With a 4:1 BalUn transformer, such an antenna can be easily used for the 25M SWBC band without an amplifier.

I went through months of building and testing loops of various diamters, turns, and conductor diameters for my 2-part series on active loops in the Jul/Aug and Sep/Oct 2003 issues of QEX.

From: msznh
Topic: 5342 Message: 5342

I'm getting rid of some good stuff that a SWL might be interested in.
Thought I'd offer this here before I go to Ebay or Craigslist.

This is for SWL/Receive mode only. NOT for transmission.

I have a never-been-used RF Systems Wideband WA-50 rf amplifier for
sale. Read up on it here:

http://www.universal-radio.com/catalog/preamps/3574.html
http://www.rf-systems.nl/pdf/wa50.pdf

I originally paid $200. Willing to let it go for $100 + S&H.

If interested contact me privately off line. US & Canada only.

Tom

That sounds pretty hard, oops, my mistake, I got the wrong one. Ok let me explain, there is a shortwave loop antenna that I want to plan on building soon a company called MTM Scientific made and they sell it as a kit and I wanted to learn more about how to build one with readably available parts . I saw this kit and I thought it would be fun to build since there is a frame and wire and other parts and pieces. If not possible I guess I will have to buy this kit soon. I am still considering getting myself a copy of the JJ Carrs Loop Antenna Handbook for me to study when I am bored. Thanks for the help, its really appreciated.

Hello,

We are using antenna to OT and OC made with ferrite, frequency coverage of 1500 khz ~ 16 Mhz. Its construction is simple, and use the device to signal with inducer. The results were satisfactory. If you have interest can send the scheme.

Respectfully,

Hi,

The example you give is a tuned loop hung a few feet from the listening position. All you need are 2 sticks, a bit or wire, a bit of coax with an appropriate connector (connects to your receiver antenna input), a tuning capacitor (looks like a standard 350 pfd ... which you can scrounge from old mantel radios). Some tape, some tie wraps and a couple of solder connections. The diagram and photos on web site are pretty accurate. Size is not critical ... but approx 2' to 3' per side will do. I guarantee it will work better than a whip antenna. I have used similar antennae and I usually orient the loop for minimum RFI noise and tune the capacitor for maximum noise. I used tie wraps to fasten the 2 sticks in the cross ... and drill holes in the ends of the sticks and use tie wraps again to fasten the wire.

The small loop in the center is the pickup loop ... rule of thumb is 20% the size of the larger loop. It does not have to be in the center ... and you can experiment on the best placement .... again the good old tie wraps hold it and the coax feed line in place. I don't know how much they are charging for the kit .... if it is reasonable ... it saves looking around for the individual pieces.

Jim

That is a nice LOOP kit and it is for MW or for AM radio broadcast, not SW.

Yea you can copy that very easy, make an X frame with 2' sides, wrap some wire (magnet, insulated, almost any really) around it to a AIR Capacitor and you have a tunable passive loop. Here is a GOOD BASIC LOOP LINK:

http://www.mindspring.com/~loop_antenna/

You can copy his design exactly. The kit you talk of saves you from scrounging for all the parts. There are not that many parts, but if you don't have it you have to get it. THE DESIGN IS 100 YEARS OLD, no state secret.

You can make an untuned LOOP with out the capacitor. I just made one out of a 1' x 1' pizza box and about 22' of wire, no capacitor. It works well for my needs, to bring in a few near by AM stations. The radio in question has no internal loop or loop-stick so I needed something. It probably came with an untuned loop, no doubt that I lost. Here is a link to the ultimate AM antenna and a pic of one I built like it (I went 5 turns because I had the wire):

http://members.cox.net/rwagoner/columns/am_antenna.html

Here is my last post of thread on this antenna with pictures:
http://groups.yahoo.com/group/loopantennas/message/5333

HOW DOES IT (tuned passive loops) WORK. The best explanation is a swinging pendulum held in you hand. For a given weight hanging off a string of given length, if you move your hand back and forth at a certain rate (frequency) the weight at the end will react in a given way. If you get the rate of hand moving back and forth just right (for the string length & weight) it will swing wide (resonance). If you move your hand back and forth faster or slower, the pendulum will not move as vigorously or with regular movement. If you increase or decrease the weight or length of string, it will react differently to different freq of hand movement. SO WHAT DOES THAT HAVE TO DO WITH A LOOP. Well the input or hand movement is the radio signal (frequency). The string length is the length of the loop, and the weight is the CAPACITOR! If you get the length of loop (number of wraps around a frame of X circumference) and capacitor (weight at end of string) just right for a given radio freq (hand movement) you get the most resonance.

If you google LOOP antenna you will find web links for calculating the range of "resonance" for a given loop, size, number of turns and

capacitor (capacitance) range.

The kit in question, if you varnish it and take your time will be
nice to look at and listen to. Like all passive loops, you have to
aim them and tune them. Of course you can make your own for cheaper.
The most expensive part is the air capacitor which is about $15-$20.

Cheers George

5351. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-07-01 22:23:47 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 5351

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.
http://members.cts.com/king/j/jlkolb/site/dif_fet.pdf

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

* Select-A-Tenna Model #541M (Passive)
- - - http://www.selectatenna.com/

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

5353. experience with this "new" broadband loop ?

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-06-30 15:49:32 UTC
From: Gerhard Baumgartner
Topic: 5353 Message: 5353

hi from austria,

i would like to build a broadband loop (50khz - 30 mhz) for my perseus sdr.
i found a very interesting curcuit- and building plan here
http://wl1030.com/content/ and there was a group which has build several
broadband loops http://www.ng-ronde.nl/wl1030/ . those who are interested in
this loop can download the general info of this loop here, it´s the file
"WL1030":
http://www.4shared.com/account/dir/6459794/8254f480/sharing.html?rnd=0

does anyone of you already built such a loop or heard something about it´s
usefulness in practice? any comment is welcome!

thx
gerhard

Hallo Gerhard

my only comment is that the OP AMPs while very good do not offer the noise floor obtainable with other circuits such as those of Chris Trask and the original Norton ampifiers. Lankford in a recent post shows his remaining interest in push pull Norton amps.

However, as Chris has pointed out we need a solution wherein the amplifier's characteristics need to be somewhat constant with the frequency varying value of the loop impedance to be optimally useful.

so after some consideration a year back I decided to wait after I can looked carefully at the Dutch site.

best

Paul in Guelph von KANADA

I've been looking at the loop impedance problem. There is a paper by a
group of Russian HF radio astronomers who have a procedure for matching
short dipoles to 75-ohms over a wide bandwidth, and I'm going to see if
their synthesis procedure can be used to match a loop over a wide bandwidth.
Problem is that the loop is a low resistance in series with an inductance,
whereas the dipole is a large resistance in series with a small capacitor.
At first glance, it seems that the synthesis procedure for the loop is a
dual of the one for the dipole. If that proves to be true, then it should
be relatively simple.
```

The Russians followed the matching network with a two-stage balanced lossless feedback amplifier. That's a bit ambitious, but they are dealing with extremely small signal levels and they need a good high dynamic range amplfier to accomplish their goal.

****

My gut feel here Chris is likely you have it in the dual mathematics as you have noted above. Very good.

It can be a most important result to recognize "duals" in problems as sometimes the dual is easier to implement.However here I guess we are changing capacitance for inductance but perhaps resistance for mhos (some JFET configuration as it is a transconductance device). So look at the paper and see if this makes sense. An inverse dual? is another notion here

best wishes and good thinking

Paul

chris and paul,

thx for your comments to this very interesting and delicate topic. now i
don´t wonder anymore why i didn´t find much in the internet about broadband
loops for selfbuilders.

info for the other members of this group. have a look in this group
"Shortwave-SWL-Antenna@...m", i posted there the question too and
chris chris answered, might be of interest to you.

paul you wrote:

don´t understand the meaning, would you please explain? hope i asked
politely, don´t know how to use the subtle nuances in the english language.

looking forward what comes next in this amp-topic. it would be great if
there is a selftuning broadband loop for selfbuilders.

best
gerhard

> That is a nice LOOP kit and it is for MW or for AM radio broadcast,
> not SW.

He's referring to this loop at MTM Scientific:

http://www.mtmscientific.com/swloop.html

No, actually that loop is for SW. It is a 1 turn loop with a 9.5-365
pf variable cap. If your run 1 turn loops of various reasonable
sizes through the calculators online, including Bruce Carter's, they
will fall in the SW range.

http://www.mindspring.com/~loop_antenna/umr_emc_calc.htm

Using that calculator, 1 turn, 36" sides, gives 3.8 mhz - 23.6 mhz.

With 1 turn, 30" sides, it gives 4.2 mhz - 27.2 mhz.

If 1 turn, 24" sides, it gives 4.8 mhz -29.8 mhz.

MTM scientific has a 15 turn tuned loop, 17" sides, that covers the
MW/AM band:

http://www.mtmscientific.com/loop.html

I have photos of my MTM AM loop in the Photos section in the Loop
Kits folder.

****

sorry the problem was my english

I meant to say I looked very closely at the design of the Dutch amp and decided it was not good enough on noise as compared to existing other amps such as those of Chris and Dallas. It was the noise in the OP AMP that bother me. The OP AMP is a good solution except for the noise floor being to high.

hope that helps

paul,
your comments sound promising, but i can´t transform them to the reality
of a working circuit. i simply miss the knowledge do to that for myself.

can you tell me exactly (part and value) what has to be changed in the
published circuit of the wl1030 to make it work properly.

or can you tell me which amp circuit i should take instead. but i need a
circuit with exact values.

i will have a look at chris paper http://tinyurl.com/ytsf6k the next days to
see if i can handle
anything of it alone. i am used to do some math as i work also on noise
analysis of random
processes - found out that there are structures in the noise but they are
fractally
dispersed and correlated with cosmic attractors, cause of noise it not
(always) anisotropic - but this
has basically nothing to do with the knowledge of electronic circuits. so
will see what i
can bring out for myself of chris paper.

can you tell me exactly (part and value) what has to be changed in the
published circuit of the wl1030 to make it work properly.

It will work but just might be more noisy. What I can suggest is to tackle the other end by purchasing a DSP audio filter like the West Mountain ClearSpeech from hamcity.com.

This is what Chris is now trying to do to define a circuit that would work well so I think I will defer to Chris here.but I do suggest anyways for listening to have a good modern DSP and certainly the ClearSpeech is a good one

http://www.hamcity.com/detail.aspx?ID=1878
here is where you can buy it best price, with your High EURO it might be a good deal.
I also use a Sounds Sweet speaker on my audio output as well.http://www.soundssweet.com/

this does not address the noise problem per se in the rf amp but can help with the audio noise reduction available via the DSP and the good less hiss speaker

best
Paul

No, it's out of the journal "Experimental Astronomy" and you can't access it online except with an account. I access it at the university engineering library. I just tried uploading it into the group files section, but it didn't accept it, probably because it's a little more than 3M in size.

Topic: 5335 Message: 5364

Hal S. said, "4. Twist the wire ends together approximately 2 turns per inch (I made a change here. On the base, I installed a two-wire terminal so I could easily connect a different length lead wire. I connected the ends of the wire from the loop to the terminal block and then connected a shielded wire to the terminal block to act as a lead-in. The ground (shield) lead connects to the ground terminal of the radio, the center wire connects to the "external AM antenna" terminal of the radio. You may have to experiment with your own radio to find what works best)."

Hal,
1. Do I understand you twist the antenna loop ends together?
2. What is "approximately 2 turns per inch?"
3. What is the "two-wire terminal" and how do you fashion two wires if the antenna ends are twisted together?
4. What kind of terminal block do you describe?
5. What kind of shielded wire do you use for the terminal block?
6. Once built, is there any kind of tuning, V-cap or does the radio receiver need to be in close proximity?

Hi Bill

I'm not sure what the original reference was, so don't have any details of
this particular loop and can't comment on any of the other questions, but this
won't mean twist together in the sense of a tight twist just to join right at
the very end.

The implication seems to me that you should expect to have some wire "ends",
let's say each two feet long just for example, presumably after constructing
the loop, and it's these you're supposed to twist together along their
length so you end up with a twisted pair of wires.
Approximately two turns per inch will mean just that, as you twist it
together allow approx two turns every inch of wire, ie don't twist it too tight.

Not knowing the original source, I can't say exactly what you're supposed to
with it after that nor if these "ends" are from a main loop or coupling loop,
but would guess that could be the connection to your radio:-)

5366. Two Passive loops in ONE - how to - design review

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-07-07 01:46:18 UTC
From: gmcjetpilot
Topic: 5366 Message: 5366

ANY HELP OR ADVICE.

I want to make a passive loop with a high and low
range by tapping into the inductive winding in the
middle and using a using a two-in-one ganged capacitor
(some how).

Size: 2' x 2' square loop on a X wood frame.
Edge wound: 18 turns (144')
Width: 3.5" (approx)
Capacitor: 12 - 390 pf x 2 (ganged together)
Connection: Inductive and/or direct feed w/ sense loop'(s)

The AM loop calculator says the low end is about 400- 2250Khz.

Tap 1/2 way (9 turns) the high end is 800 - 4500 Khz (in theory).

I will have a secondary "sense" winding (single loop).
Not sure if one or two separate senese loops are needed for
each the high and the low ranges?

I'm not sure if I should put that SENSE wire in line
with the inductive winding, or inside the the windings.

I could put the sense loop in middle of inductive windings side,
with 8 windings on each side. However when I tap 1/2 the windings
the sense wire will be on the edge.

A better idea might be put the sense wire inside the
2' x 2' frame, for example a 1.5 foot diameter (round or
square) sense wire. That could handle both bands.

To switch between the HI and LO freq I could just
use two feed lines or have a terminal block and
connect the coaxial feed to different terminals as
needed.

I'm not sure if I need a switch to open the circuit to
the two ranges.

Any help or advice would be nice for my idea of
having a two in one loop.

Thanks George

To range switch, have you considered breaking the loop into two 9 turn sections and use a DPDT switch or relay to connect them in series or parallel? With one tuning capacitor this should jump the frequency range about 2:1. I think this gives you a higher Q and better tuning range than just letting 9 turns hang on the end of the 9 you are using.

>Thanks George

Hi George,

Yes, it is possible to use a 2 gang capacitor to simultaneously tune 2 separate inductors. One inductor ... usually the one tuning the higher frequencies will be tuned by the 2 capacitors in a series configuration. The second inductor is connected across one of the gangs. If you are using a standard 2 gang capacitor which is 350 pfd each .... then the first inductor (usually the smaller one for higher frequencies) is connected across the 2 gangs in series ... eg maximum value of 365 pfd / 2 = 182.5 while the second inductor would be connected across one of the 2 gangs eg 365 pfd.

The output would be via a link winding or link windings. It is certainly not a common method .... at least not in recent times. However, in the past this was a common method of constructing a mult-band output load for RF transmitters .... which reduces or avoids switching. You would have to look for this circuit in Radio Handbooks of a late 40's or early 50's vintage to see examples. It is also a similar concept for a version of antenna tuner (known as the Z-match) which is also a relatively old configuration (back when parallel open wire feed lines were standard). Now that multiband antennas fed with open wire line are starting to become popular again the Z-match is experiencing a resurgence. I have never seen the concept applied to small receiving loops.

I think it would be an interesting project.

Jim

Why tap in the middle, 9 tunrs. You would have a lot of wasted
overlap of the two ranges.

If instead you tapped off just 3 turns, you would have a range of
about 2000 khz - 11,000 khz. I am probablly using the same
calculator you are,

http://www.mindspring.com/~loop_antenna/amloop_calc4.htm

and using 24" x 24", .75" wide, 3 turns, 12-390 pf.

So your low range would be 18 turns, and cover 400 - 2250 khz, and
high range would be 3 turns, and cover 2000 - 11,000 khz.

>
>Jim

This is an addendum to my last posting .... I suggest a possible strategy would to consider the Z-match antenna tuner circuit. In that circuit 2 separate inductors are tuned by a single 2 gang capacitor as outlined above ... However, since you are using the inductors as antennas themselves (loops) you do not need the input link windings. In the Z-match circuit the inductors/loops are coupled to the receiver via a series capacitor which in effect produces a L match circuit. You would need a second single gang capacitor. You would then have no switching at all.

You could wind a standard loop for MW and second loop for SW ..... fit one inside the other and put them at right angles to each other to avoid interaction. Heh it sounds so good I may try it myself hi hi.

One capacitor (the 2 gang) would tune the loops, and the second capacitor would match the input to the receiver. You can find the Z-match circuit on-line. The number of turns on each loop would be experimental to some degree. It would also be possible to use a single loop with an appropriate tap ... however adjusting the relative inductances would take much more careful experimentation.

Jim

5371. 10 meter full wave loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-07-07 19:02:29 UTC
From: dannousa2002
Topic: 5371 Message: 5371

I have a 10 meter full wave loop. Apex at 25 foot each lower leg of loop is 10 foot off the ground. It works real good what you hear you can work. The only thing wrong is the rf in the shack it gets into my rotor control box and a small tv monitor next to the radio transmitter. This is the w5sdc Delta loop for hf with a 4to1 balum and fed with RG-8 coax it is also wound with 8 turns of the feed line under the antenna. No tunner needed on all of the 10 meter band. My radio yeasu 847 is grounded and the antenna tunner is also grounded but still some rf in shack. Any Idea on what to do to keep the rf outside?
Thanks
Dan

Hi Dan,

I believe W5SDC feeds his loop at the apex .... I assume you are doing so as well. I suggest you try feeding it at one of the lower corners and move the feed line out of the loop aperture. Since the bottom is only 10 ft off the ground you should have little difficulty with the experiment.

Good idea I did not think of ganging the two together.

You lost me a little but I'll do research. I really want to keep it simple. I would love to have a two band loop. The going in position is keep it simple, min parts, switches and so on.

I guess one way would be just make two loops on one frame with two feed lines or may be a toggle switch to switch from a single to ganged capacitor and loop A or B, but thanks for the great advice.

Thanks Paul makes sense. So if its just 3 turns, I'll just have a full 3 turns + 18 turns, I have 900 feet of wire to play with. Great thanks.

Thanks Jim that sounds interesting. Since this is my first real LOOP (I'm going to try and may nice looking and sounding) I may set my sights lower for a simple loop. However I'll save you post for my next loop.

I leaning to just having too loops (really quite separate) on the same frame, may be only sharing the same capacitor and sense loop wire. I may use manual switching or a terminal to swap, changing from Low to High range.

Cheers George

5375. The Tale of three Chinese Loops - comparison and pictures

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-07-11 08:57:44 UTC
From: gmcjetpilot
Topic: 5375 Message: 5375

ANY INPUT COMMENTS OR SUGGESTIONS WOULD BE APPRECIATED
(please to not cut and past this whole long post in reply)

How should I test these three loops?

The tale of three Chinese loops
http://img525.imageshack.us/img525/7522/slide3copymh0.jpg

Terk and Tucsun MW/AM passive loops
http://img522.imageshack.us/img522/4841/slide2hh6.jpg

Kaito TG34 Active MW/SW loop
http://img522.imageshack.us/img522/1176/slide1fx3.jpg

I have more experience with the (DEGEN) TG34 loop, which I have owned for many months. I have to say I am pleased with it and it always impresses me, especially since it was only a $20 option bundled with a DEGEN DE1103 radio I bought on eBay.

The two passive MW loops are the Terk AM Advantage and TECSUN AN-200. I paid about the same $30 to $34 for them. The Terk is widely avaiable in the US and the Tecsun is china and found on eBay (from seller: liypn)

The TG34 can fit in a small bag when collapse and folded up, and it has both MW and SW capability. It is not free standing and needs to be hung from something, preferably in a window. The TG34 is an active loop powered with two AAA batteries. My initial opinion or gut says the TG34 is probably better than the two passive loops overall? I still have to do some A, B & C comparisons.

All loops have the ability to connect direct or by "proximity" to the radio. The active TG34 loop has the ability to directly connect to the radio or passively with a repeater loop-stick.

The passive MW loops may do better than the TG34 when directly connected to an AM radio with antenna terminals (I think). For passive boost the TG34 may be better with it's cool little loopstick repeater you can put right on-top of the radio, for best position near the internal loop stick. On the other hand you have wires and have to tape or hold that loop-stick repeater onto the radio. The passive MW/AM loops sit next to the radio on one of 4 sides. I tried putting them on top of a Sony (where I know the internal loopstick was located). It did not work well with the loop sitting on the radio, at least with this radio. It was better off to the front or back with the edge of the loop ending where the loop stick started. If I tried to "frame" the internal loop stick in the middle it did

not work well either.

QUALITY

The two passive loops are well made but the Terk seems a little more stout (heavier) and has a nice rubberized base. The tuning knob on the Terk is thumb type in the middle with a nice pointer and freq scale (530-1600 but range goes past the scale). The rubberized thumb tuning dial is nice but a little harder to get at than the Tecsun.

The TECSUN AN-200 is pretty to look at (beauty in the eye of beholder). They both have the same dia or very close, about 9" dia. Counting the Tecsun it has 28 turns which is about 66 feet of magnetic wire, 18 gauge? The winding is tight and may have some adhesive holding them in position? The Terk winding is hidden and assembled with recessed screws. The Tecsun has no visible fasteners and looks snapped or glued together.

The Terk base is wider but not much more stable because of the higher weight of the loop housing and the base is not symmetric, in stops short on the back side and is flat, not extending past the loop as far as the base extends on the front. Minor point but it makes it want to tip backwards more. The Tecsun is more symmetric and being lighter helps, but has about the same overall stability. Neither are going to fall over on their own.

Both have 1/8" jacks to connect a cable for direct connect to the radio. The Terk AM Advantage's cable is long and terminates to bare wire. The Tecsun supplies a short cable with 1/8" phone plugs at both ends, which may or may not work with many radios AM/MW antenna connection jacks. No big deal there are workarounds for that.

TEST SO FAR

My first test was trying the passive loops on my home mini stereo that has an AM radio and no internal antenna but does have two terminals to attach an AM antenna. The results where as expected, very good with both. I really can't say one shine above the other, may be the Terk had an edge but the Tecsun AN-200 was easier to tune. For one the knob on the side was easier to get at and tune than the thumb knob. However the Terk does have a Freq scale that is pretty good. When I saw the scale I thought it might be a joke and planned on ignoring it. However its not bad for getting close. Most will just spin the knob for best signal but I can see where the scale can improve that shotgun technique add some quasi precision guessing at where to set it.

One thing I notice is the Terk seems to have a sharper null node and sweet spot. The Tecsun was not as sharp and had broader sweet spot or less sensitive. Terk with its thumb knob and freq scale was surpisingly close as I said. The Tecsun has a generic 0 - 10 scale. Both had about 180 degrees of rotation. The Tecsun tuning knob was

easier to get at and easier turn, but may be more susceptible to accidentally being changed. The Terk knob had more resistance or friction. The Tecsun was easy to spin. The Terk feel was not bad or hard to use, just not as easy.

I tried both loops in passive mode as well. I used a Sony AM/FM portable/table AC/DC radio. The results where also as expected, good, but nothing definitive yet.

I'm always impressed with LOOPS, its like PFM, Pure Freaking Magic. I could pull in a whole new station (on a different freq) by just tuning the antennas. That is amazing (can some one explain that to me)? I have had the experience where the directional nature of a loop has rejected a weak station and brought in a new station, but they both where on the same freq.

I have not had a chance to really try them out and will report back. Please let me know what you think.

Questions?

Can any one tell my why the Tecsun tuning is more mellow and seems less sensitive or wider sweet spot? It is affective but different than the Terk which is like the TG34, very sharp null and sweet.

Not enough experience to tell yet which one is better, but like I said for the money, wider band, portability, with the experience I do have so far. The TG34 sold under different names like Kaito, Degen or Generic as I have is a deal and better for a radio hobbyist. However the TG34 has many parts and has to be hung-up, and its not pretty to look at. It looks like a hanger. Behind blinds in a window its not bad.

The MW/AM Loops are very simple and free standing. When boosting a radio by proximity there are no wires or batteries. For just AM radio, home use, the passive loops are better in the MW band. The Tecsun is pretty to look at (to me). The Terk is not bad looking either; it sits lower on its base. Also the Turk's med gray tends to blend with typically gray or black radios well. The Tecsun red magnetic wire yells LOOK.

Overall all these antennas are bargains and do what you expect and probably a more, especially for the money.

I don't think these store bought passive MW/AM loops are going to be as good as a LARGE well made home-brew loop. However its hard to fit a 2-foot-by-2-foot loop on the coffee table or next to the radio on the night-stand. I recommend all three antennas, and if I get any more info I'll pass it along.

ANY INPUT COMMENTS OR SUGGESTIONS WOULD BE APPRECIATED

Cheers George

An educated guess says the Tecsun is not as sharp because they used (from looks of picture) many many turns of small gauge wire. They probably chose this approach for aesthetic appeal (sure looks good doesn't it) because it actually works against the performance of the antenna.

CORRECTION I mislabled the pics

How should I test these three loops?

The tale of three Chinese loops
http://img525.imageshack.us/img525/7522/slide3copymh0.jpg

Terk and Tecsun MW/AM passive loops
http://img522.imageshack.us/img522/1176/slide1fx3.jpg

Kaito TG34 Active MW/SW loop

** TOO MANY TURNS **

???????? "many many turns of small gauge wire" ????????

It has 28 turns, which is about right according to the Loop Antenna
Calculator.

I just noticed on the inside of the loop there are three turns in the
middle, under the induction winding; this must be the sense wire for
the direct connection.

You say too many turns of small gage wire? Does wire gage have
anything to do with it? If limited to 9" dia loop than how many turns
do you need? With the loop calculator a 10-365 pf cap 28 turns gives
550 Khz -3380 Khz around a 7" x 7" frame (the calculator is for
square loops, so 7"x7" is equiv to 9" round in circumference or wire
length per turn).

I wounder what the TERK has inside. There are screws to disassemble
but something tells me not to to take this one apart.

** TUNING SENSITIVITY **

I have to say the Tecsun AN-200 has about the same gain as the Terk
in performance, from what I can tell. I am hard pressed to say there
is a big difference between the two passive loops. It is just that
the Tecsun has a less sharp edge tuning characteristic. I don't want
to say less sensitive, just not AS SENSITIVE to tuning the CAP.

Speaking of tuning sensitivity, the TG34 active loop is SUPER
SENSITIVE and with a tiny thumbnail tuning dial, it takes a precise

touch to get it dialed in.

** TEST CONTINUES **

Since I last wrote, I tried all three loops with my Degen DE1103. The Degen must be maxed out already with the existing internal loop stick, because none of the loops produce a significant gain. The DE1103 does have an antenna jack input but not for MW, only for SW. I'll try the MW loops on 160 meter.

I also revisited the Sony AM/FM portable/table radio. All loops produce obvious and some times dramatic difference. I got the TG34 out for side-by-side comparison to the passive loops.

** UPDATED CONCLUSION SO FAR **

As I thought and remembered, the TG34 does a little better with its amplification and loop-stick repeater for "proximity" signal boosting on the Sony table AM radio. The down side are the exta wires and trying to position the soft loop in the window, which can be a pain. Some stations are better with the loop perpendicular to the window (N-S), other stations are better with loop flush to the window (E-W) direction. I have to jury rig a support out from the top of the window to hang the loop from, than tether to keep it from turning.

Tuning sensitivity of the TG34 with a small thumbnail dial on the small amplifier module (the size of a large pack of gum) makes tuning more touchy and harder than the others, at least with out practice. Its easy to overshoot (again). Very small movement of tuning dial makes a big difference. Of course the TG34 can do SW and is pretty good up to about 9-13Mhz.

The passive loops are just right for the portable or table top AM radio on a table. They are both nice, the Terk AM advantage and Tecsun AN-200 are worth a look. I'm probably going to keep both, and if have to decide on one, the choice would be hard. I would lean more towards the Terk only because it comes with a better cord to connect to radio and may be (?) a tad bit more gain (may be). However style wise, the Tecsun AN-200 is pretty flashy. If the wife is involved this would be a good one for her to decide based on style aesthetics alone, since they perform pretty close.

MORE test to come? I'll keep you posted if I find anything else.

Cheers George

You haven't really described how you're testing the loops. For MW, the testing should be done during the day, preferably in the early afternoon. Skywave reception at night makes accurate testing virtually impossible. In the day time you're getting almost all ground wave, which will not vary significantly during the time of the test.

To test gain, find a station that's just barely perceptible on the radio with the internal antenna. Even better, tune to a station you know is there but is just out of range on the barefoot radio. This gives you enough head room to get some idea of how much gain the antennas are providing.

Another important characteristic of a MW antenna is the ability to null interfering stations. For this you need to find a fairly strong station that's masking another station. Rotate the antennas until the strong station begins to fade. Keep adjusting to minimize the strong station. Can you know get a decent signal from the station that was masked? The masked station will need to be at an angle to the stronger station. The closer to 90 degrees, the easier it will be to null one and receive the other.

Finally, the sharpness of the null produced by an antenna can be an important characteristic. For this you need to find two interfering stations that form a fairly narrow angle from your location. You'll probably have to experiment to find a situation where at least one of the antennas makes a difference in reception and compare the others to that.

Hope this helps.

George;

Nice job reporting test results. I need to embellish my statement about the Tecsun having many many turns (I was tired and did not say it correctly).

I've only built larger loops, starting at 2 ft. They need 15 turns or so for a std. 15pf-360pf capacitor. 28 turns seems like alot but given it resonates, the number of turns is obviously matched with the correct value variable capacitor. A possible reason why the "Q" is low and tuning is wide is because the turns are very close together. It is a known fact inter-winding capacitance plays a role in loops and Q is reduced (ie, bandwidth is wider) with closer spacing of windings. As to why the Terk's bandwidth is tighter than the Tecsun, given the width of the loops appears to be about the same - I don't know without seeing the windings. One possibility is the Terk uses Litz wire which, by it's design, reduces inter-winding capacitance.

Keep us posted if you take the Terk apart.

Mark

Hi Mark:

Roger that, the turns are close together (touching) and clearly spreading them out improves the low end.

I just did my final test this time with a Ten Tec RX320D (PC radio).

Using the S-meter was better. I ran all of them through a 30:1 balun.

I also compared the three loops to may main antenna, a 60 foot random wire, approx 15-20 feet above ground, with 30:1 balun, grounded of course.

The pecking order (MW band) is:

Random wire
TG34 amplified loop
Terk Am Advantage
Tecsun AN-200

The random wire is better than the TG34 and both passove loops. The random wire random wire is significantly better than the two passive loops. The TG34 was also much better than the two passive loops.

The two passive loops are close, but clearly of the two passive table top loops, the Terk has a bit more uhumph, based on my S-meter. Sound wise it was hard to tell, but on one station I though the Terk had lower noise or static.

Surprisingly the random wire was more quiet, at least on the few stations I checked, but not always. Keeping in mind the random wire is outside and the two loops I had in a 2nd floor window sill, but near by CRT computer monitor, which no doubt added noise.

Conclusion loops are awesome but just one tool in the antenna bag of tricks.

My next antenna actually will be a 2' x 2' loop on an "X" frame. I just got the air capacitor in the mail. I expect to blow the 9" loops away. Bigger is better.

One day I'll have room for a real long wire and/or a
Wellbrook Loop on a rotor.

Thanks for the input.

George; Sounds like you are having fun :)

Couple thingies to pass on ... a) I have found a practical limit to "bigger is better" .... my 2 ft loop (15 turns of 20 ga (or is it 22 ga) solid copper is my best BCB loop 9 out of 10 times as opp to my 3.5 ft loop. Why? Combination of ease of use (rotation/placement) and enough gain to grab the really weak ones (daytime signals). The big loop with much bigger aperture and more gain seems to hit a theretical point of "no more returns" at my QTH where residual noise becomes the bigger issue. Have I "maxxed out" for my QTH? Perhaps. But maybe not. I've yet to get my end-fed sloper up - perhaps that will surprise me. But what really surprised me was this setup: I have a CCrane Twin-Ferrite as well as the 2 ft loop and 3.5 ft loop. Each on it's own gives me a significant gain and better s/n ratio on BCB than a barefoot radio. I'd been using inductive coupling with the loops, direct coupling with the T-F. One day I got a little crazy and direct-connected the T-F, setting its ferrite head next to the 2 ft loop which was sitting on a Lazy Susan. --> YES!!!!!! <--
The sum betters each individual contribution. I am now getting more gain & improved s/n ratio using a combo of the two antennas. I mostly spin the loop for direction but sometimes orienting the T-F head and playing it's sweet/null points against the loops seems to give me more null options. At any rate, this is a DX setup and not too gangly and unwieldy. Perhaps someday I'll have a chance to put this setup against a Quantum to see how it fairs for gain and null. The Quantum, with it's Q multiplier, will always win in the Q department.

b) I wonder about the performance difference between loops and long wire and the 30:1 balun. I'm still attempting to become an antenna expert (I'll let you know if/when I ever get there :) but from reading, most end-fed long wires use a balun ranging from 4:1 to 9:1. 30:1 seems like a huge ratio. Can you elaborate on that? Is this a store-bought or a home brew antenna? Did you wind the balun? Where did you get plans?

And I wonder about using the 30:1 balun with your loops. They both have sense loops for direct-connect, correct? Wouldn't

direct-connecting yield more gain? Or is your rcvr loading down the sense loop so you've connected a balun in between? I ask also because I have a TG 34 and although I've never done a side-by-side with a BCB loop, it never struck me as being as good a BCB antenna compared to the multi-turn passive loops. Hmmm. Maybe I need to re-evaluate? Or is the use of a 30:1 balun with the Terk & Tecsun hurting performance?

Hope you can post more results. Good so far.

Mark

Just read this and was interested to see the results. Only a couple of comments on this test though....

1. I am not sure what was meant by the comment "Using the S-meter was better. I ran all of them through a 30:1 balun."

The TG34 has an output impedance of approx 50 Ohms so why would you put it into an impedance transformer ? (30:1 is one heck of an impedance change)

2. Why was the S-Meter the measurement tool of choice ? An S-Meter does not deliver a Signal to Noise ratio indication. It is well known that Loops, active or passive, often produce less Signal strength but that really is not the point. The signal to noise ratio is the key performance indicator, provided the loop produces enough RF output to overcome the noise floor of the receiver. Most modern HF receivers are quiet enough and have enough AGC range to cope with the low RF output of a decent loop. It is also worth noting that the Ten-Tec is "hobbled" on frequencies below 2 MHz as a feature of it's design so sensitivity is greatly reduced (I own an RX320 as well)

Jut some food for thought and don't forget that when comparing a long wire aerial (antenna) with a loop, you are comparing E field and an H field aerials ..... they behave totally differently when placed in noisy (i.e domestic) RF environments ;-)

Best Wishes

Fraser

Hi Mark,

The multi-inductor (loop) front end is superior to most single loop systems. There is a lot of good reading about this in 'crystal radio' web sites. I have experimented extensively with long wire antennas on MW (out at the farm) where there is no local RFI to deal with. I used direct connection to MW antenna terminals on such radios as the SRIII etc. and the normal 50 ohm input of radios such as the TS-50. There is some improvement using a RF transformer. However, My eyes were opened when I used the wire in conjunction with a HighQ loop. If you configure the loop as an 'antenna tuner' with a second wire as a counterpoise. It is possible to get the same performance with small (non-loop) High Q inductors in conjunction with the long wire.

However, in an environment with RFI the performance of the long wire is diminished as the S/N ratio is not as good as with a tuned loop alone. to maximize MW performance from a long wire a High Q antenna tuner with counterpoise is required. I have not been able to achieve the same level with RF transformers ... eg wound on ferrite cores.

Jim

Oh, oh!

I was just wondering by myself, that if people have their PC Monitor opened, when they are testing such small loops or other active or non-active antennas situated in their room, are they not able to think, that that may not be the most wise method to do things? At least it is not fair for those tests, not at all!

So, let us close all possible sources of RFI (Radio Frequency Interference) in our home, when possible, if we want to receive just results, when doing such comparisons.
I just counted, how many pairs of outputs (electricity holes) I have in my radio room. 52! How many computers and Monitors? 3. How many lamps? 9. How many Radio Receivers? 14. Plus 3 printers, 1 paper tearing machine, 3 pairs of active loudspeakers. 3 telephones.Then about antennas, how many? 9 coaxial cables coming from the upper and lower roofs. 32 different active and non-active loops and other types of antennas. (I am a very enthusiastic home-brewer of antennas and crystal receivers and other radio device.)

This just to tell the reader, that there really may be a lot of things in use or not in one room to do the antenna-tests in a right or wrong manner.....
Best wishes!
Aimo

Just read this and was interested to see the results. Only a couple

of comments on this test though....

1. I am not sure what was meant by the comment "Using the S-meter was

better. I ran all of them through a 30:1 balun."

The TG34 has an output impedance of approx 50 Ohms so why would you

put it into an impedance transformer ? (30:1 is one heck of an

impedance change)

2. Why was the S-Meter the measurement tool of choice ? An S-Meter does not deliver a Signal to Noise ratio indication. It is well known that Loops, active or passive, often produce less Signal strength but that really is not the point. The signal to noise ratio is the key performance indicator, provided the loop produces enough RF output to overcome the noise floor of the receiver. Most modern HF receivers are quiet enough and have enough AGC range to cope with the low RF output of a decent loop. It is also worth noting that the Ten-Tec is "hobbled" on frequencies below 2 MHz as a feature of it's design so sensitivity is greatly reduced (I own an RX320 as well)

Jut some food for thought and don't forget that when comparing a long wire aerial (antenna) with a loop, you are comparing E field and an H field aerials ..... they behave totally differently when placed in noisy (i.e domestic) RF environments ;-)

Best Wishes

Fraser

What about if the compared antennas all have the same advantage of height?
Should they not be tested equally?
Only then we could see and hear, what they are capable of!
Just my humble opinion.
It is said to be a fact, that on BCB the corresponding loop will give the best results, when it is near the earth level, right?
But if we test a random wire on the same level, what might be the results?
I have been testing the small Chinese loops from Degen on my roof with good results...

Most of the radio listeners are not able to put their antennas outside. So, we are very often just talking for the people, who have a lot of room outside and permission to erect a decent antenna, are we not? But they are a very small minority of the whole lot of people on this planet, right?
Best regards!

Aimo

Hi Mark:

Roger that, the turns are close together (touching)

and clearly spreading them out improves the low end.

I just did my final test this time with a Ten Tec

RX320D (PC radio).

Using the S-meter was better. I ran all of them

through a 30:1 balun.

I also compared the three loops to may main

antenna, a 60 foot random wire, approx 15-20 feet

above ground, with 30:1 balun, grounded of course.

The pecking order (MW band) is:

Random wire

TG34 amplified loop

Terk Am Advantage

Tecsun AN-200

The random wire is better than the TG34 and both passove loops. The random wire random wire is significantly better than the two passive loops.

The TG34 was also much better than the two passive loops.

The two passive loops are close, but clearly of the two passive table top loops, the Terk has a bit more uhumph, based on my S-meter. Sound wise it was hard to tell, but on one station I though the Terk had lower noise or static.

Surprisingly the random wire was more quiet, at least on the few stations I checked, but not always.

Keeping in mind the random wire is outside and the two loops I had in a 2nd floor window sill, but near by CRT computer monitor, which no doubt added noise.

Conclusion loops are awesome but just one tool in the antenna bag of tricks.

My next antenna actually will be a 2' x 2' loop on an "X" frame. I just got the air capacitor in the mail. I expect to blow the 9" loops away. Bigger is better.

One day I'll have room for a real long wire and/or a Wellbrook Loop on a rotor.

Thanks for the input.

5388. An Inexpensive Alternative to the WL1030

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-07-13 23:56:57 UTC
From: Chris Trask
Topic: 5388 Message: 5388

I've been working steadily on this project ever since it came up. Paul Birke, a member of this list, has been stirring the pot with various ideas, and last week I had a fully working active loop antenna:

http://tinyurl.com/5zeewv

I have not tested the first one shown in this document, only the second one as it had much more favourable mechanical aspects that were well worth pursuing. These active loops do not have any frequency compensation as that part of the task proved to be much more demanding than I had anticipated.

I'm presently working on a more advanced version that is frequency compensated, but it may be some time before I have it completed. In the meantime, these amplifiers are both usable, the only difference between them being the loop coupling transformer. That transformer isolates the loop from the electronics (an essential design consideration), as well as providing the first defense against common-m?de EMI and IMD products from strong nearby MW broadcast stations.

You will notice that the parts cost for both of these is around $30, which is far less expensive than the WL1030 or any of the Wellbrook products. That was the essential goal of this project.

Chris

MISTAKE.....good catch.

Yea I meant 9:1 and I hand wound a toroid 31:11 turns (interlaced or overlapped). Usually the balun ratio is 30:10 so I had 30 on my mind.

As far as the loops I was playing around more at night where some normally strong stations don't peg the needle because they drop power and go directional so I am on the back side of the main target.

The Terk loop did pull in more signal than the random wire/end fed.

Good catch 9:1 not 30.....30 turns is what I had on my mind.

>b) I wonder about the performance difference between loops and long
>wire and the 30:1 balun. I'm still attempting to become an antenna

5393. AOR LA390 Active Loop Antenna Appraisal

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-07-14 15:16:28 UTC
From: w_w_williamson
Topic: 5393 Message: 5393

I posted this message on the Eton E1 Group and I thought it might be of interest to people here so I've copied it:

My LA390 has arrived safely and is working well. It is solidly built with a heavy metal base unit which keeps everything stable with no risk of falling over. The band selector knob is large and very positive. The fine tune knob is smooth and covers a wide range with a sharp gain peak which makes tuning easy. Both knobs are marked to show their positions. The Loop swivels freely on it's BNC connector, so there is no need to move the base. AORUK made me a "patch lead" with a PAL connector for the E1 and a BNC connector for the LA390 so there was no need for an adapter.

The Wall Wart is larger than the E1's and it's output is rated at 12V 500mA and claims to be "low noise". There is also a 9V regulator built-in the base unit. The Loop draws just 80mA so the power supply is not over-stretched at all.

The frequency bands chosen are very convenient and cover the following ranges:

1. 150-800kHz (Longwave 148.5-283.5kHz).
2. 700khz-3Mhz (Mediumwave 520-1710khz).
3. 3-10Mhz (Shortwave bands 100-30 meters).
4. 10-30MHz (Shortwavw bands 30-7.5 meters).
5. 10kHz-500MHz (Loop acts as amplified whip).

RFI is significantly less on all bands and I'm even able to sit the Loop next to my wireless router without interference. Interestingly, the reduction in RFI is much greater than that achieved by using my multi-socket mains adapter with it's built-in smoothing.

Selecting the correct Loop band and using the tuning knob for maximum signal gives better results than the E1 whip. Rotating the loop gives further gain and/or nulls unwanted noise/signals. Switching between the Loop and the Whip highlights the difference in performance with signals on the E1 Whip being much lower or missing in the RFI.

There was a Ham DX contest last Saturday and I was able to listen to them on the 160 meter and 15 meter bands for the first time.

The LA390 shows a significant improvement over the E1 Whip in terms of RFI and performance and would suit anyone looking for an indoor or portable solution.

From: gmcjetpilot
Topic: 5375 Message: 5394

Again 9:1 not 30:1 my bad......

Good point why use the balun with the loop. Don't know I'll try with out. I was thinking wire input = 300 ohm, like a TV. I as also thinking 66 feet of wire but forgot about the SENSE wire couple. I really don't know what the impedance of the loop, but you say its already 50 ohm? Cool. The AM radio does not say what input impedance is? The FM is labeled 75 ohm.

S-meter? Yea why use it? Because it is the only thing I had to use besides my ear. As I said my Mark IV calibrated ear says: Less static, louder (aka stronger signal), better S/N etc...... Often its too close to tell by ear.

As I was saying, on a strong station (turned down the juice at night they don't peg the needle) the loop was better than the wire. However any antenna will bring it in. With the S-meter I was able to make a quantitative reading. However your comment about signal and S/N is well taken and why my calibrates Mk IV-E ears are a good indicator.

The LOOP did better with the "stong" case in Par above, "soft pegged" the needle (this is a RX320D, PC Radio so its all on the computer), where the wire was floating around in the S-7's. Very small difference really. The AN-200 was about the same as the wire and did not soft peg the 10 on the **point-tee-thing (ha-ha). So I can only gather the Terk AM Advantage has more Q than the AN-200. Again the EAR said all same.

**(Note: S-meter on DX320D is software dependant - on the software I was using, the signal strength meter scale was out of 10. Also most RX320D software allows the user to "calabrate" or put a scale factor in, so the actual number means nothing, relative to spacific "S-meter" standards. However it is excellent for A-B comparisons.)

Radio RX320D: I know the radio is intentionally de-tuning for the MW to avoid over-driving with strong AM BCB. There are two mods that make it a MW and LF king monster. One, a very simple Cap bypass on the antenna input, which makes it have significant gain to 100khz (and below but most software controllers only allow tuning to 100Khz). The other mod is a different transformer, which, a little more involved mod. The Euro crowd loves LF and VLF more than the US radio market. They do these mods on this radio all the time. I know there are LF stations in the EU. In the states with so many 50KW AM stations they can overdrive the radio and cause problems on LF and SW freqs. My radio is stock.

Good point on the E and M type antenna. I know bairly enough the
understand what you are saying. With my experience I understand what
you mean. Since a wrote as I said the LOOP showed better S/N than the
end fed, but you are right they are different and switching between
the two I am getting the hang of what they can do or not do.

Cheers George

Yes, they all are the same height. The loops where all "tested" in a second floor, south facing, window, hanging or sitting on the sill.

The window frame is all plastic and the window screen and screen frame are also plastic. There may be some metal clips in there.

The Loops had a pretty good clear view of the south and to the E-W (which seems to be the location of most stations due to larger radio markets at the same latitude. Although there are many stations to the south, requiring turning the loop 90 degrees. I suspect the North stations are attenuated somewhat due to house structure, but that radio waves can bounce around anyway.

The wire is coming out the same second floor window where the loops. are. I tried to keep the loop away from the antenna wire and ground wire, and doubt there was much if any interaction. The wire goes from house to a tree. The feed line is coaxial through same window. GOOD FEEDBACK!

As I was saying the Loops where near a CRT computer monitor. However I unplugged and it did not seem to make a difference. Also per my previous post there where some stations where clearly the LOOPS noise rejection characteristic shinned more then the random wire, which may have had stronger signal (s-meter or loudness) but also sometimes a higher noise floor, aka S/N ratio. BE SURE LOOPS ROCK. Now to the PLUS column of random wire, you don't NEED to point it or tune it (although you can / should for max performance).

I think every loop should have an omni-directional antenna buddy on an antenna switch for serious scanning. Loops are more work in some ways than random listening. However for targeted freqs, loops rock for size, cost and the performance possible. It is also ideal if you can fit a random wire. I was challenged to get the random wire I have in onto my small lot, and I still worry the HOA will send me a letter telling me to take it down. (I just read the rules and they go into satellite dish size, but states they require "architectural plans" and approval of any out door antenna! May be I should submit it. You can hardly see it. Its 22 awg stranded with white PTFE insulation. I am thinking of putting a LOOP in the tree with a rotor and remote tuning! The HOA does not allow antenna above the roof line. There is the attic but I think out door and away for house (RFI) is goodness.

Cheers George

I am not be wise (ha-ha) but I had the CRT off with the portable radio. I eliminated the the CRT by unplugging it.

Also I can and do actually run my PC RADIO (Ten Tec RX320D) with out CRT or computer running some times. I have a Palm Pilot with software that allows me to tune the RX320D, and it even has a S-meter display.

The other method to run the RX320D with out computer is tune it with the computer and turn the computer CRT and computer off (unplug). The radio will continue to run at last freq and settings, but you don't have any control of vol or have a S-meter. The RX320D is turned on and off with a toggle switch on the black box itself.

The test I did with a AM/FM/CD/Tape Awia mini-stereo (with no internal AM antenna) was tested was down stairs, away from the CRT. There is a LCD TV, which does give off noise if real close. Fortunately is out of line from most of the stations. I only compared the Terk and Tecsun on the Stereo. All other comparisons with the portable and RX320D was done upstairs. I wrote about the 1' x 1' pizza box non-tuned loop I made for this Aiwa stereo. It does pretty good on the two powerful stations to the east (and yes the wall its on is E-W), and hard pressed to tell the diff on those two stations. However after trying all the AM stations I should be able to get (according to the Radio Locate web site), I have to say the Awia is not a AM radio DX machine. Also being down stairs, not by a window and with a few internal walls in the way, reduces LOOP performance.

RFI Expert? (well at least for my installation)

A really good point about noise but let me say I have a lot experience with this. When I first got the RX320D I had a heck of a time with RFI. The RX320D is tied to a computer, so its a necessary evil. After much time and effort I found where all the noise was coming from and what worked antenna wise. I went around with a portable SW radio looking for local noise. Yes the CRT, Computer, Mouse(wireless) and even key board (wired) give off some near RFI, but you almost have to touch it with the whip antenna. The WiFi at 2.4Ghz was not a factor.

The real culprit was the scanner/printer combo, even in idle, it was a radio station from 17-23Mhz. The mouse obliterates the 11 meter 27Mhz band, but only when moving the mouse. The CRT was not bad unless you're almost touching it. The test "WINDOW" is about 6 feet away, not perfect but acceptable. I found little ore no diff with CRT on or off, but that was because the loops where not pointed right at it.

Again I did find stations and senerios where the LOOP had clearly better S/N ratio than the random wire.

When I first got my RX320D it was terrible with an indoor amplified mono poll antenna, S/N ratio wise. It was not till I strung the random wire outside, with a coaxial feed, ground with a 9:1 balun did I get it the RX320D to sing. Since I have DX'ed New Zealand and Kuwait in DRM! That blows me away. The antenna is not great just workable, but does indicate what a good radio the RX320D is.

My random wire needs help still, in that it comes up to the window before transition to coaxial, where the ground wire taps in as well. I need to move the wire antenna end feed termination on a non-conductive tether, away from the house, verse right at the window. I have been so happy and impressed with the performance, so I have not bothered to improve the wire antenna.

The CRT, if it had a large affect on the loops, it would affect the wire antenna somewhat as well, since all have some part approx the same distance from the CRT.

THANKS FOR THE GREAT COMMENTS GUYS (gals?). George

Ha-ha, OK I love a stickler for details. Good catch. Now that you brought it up, can you enlighten me how the math is derived.

I just copied a design off the web that was measured or reported to be 9:1. 30:10 is more traditional but recall the extra turn was to compensate for something, which I don't recall. I believe what he did was wind it, test it on the radio and than added turns. I suspect my shorter random wire is less than 450 ohms. No random wire is not exactly 450 ohms. I read 300-600 ohms is typical, so 450 ohm is right in the mid range.

HOW DO YOU MEASURE antenna or balun impedance? Does it take lab equipment? Is it possible to measure it exactly? I suppose it's possible, but how it reacts under a particular RF is another issue, right? (0r is it easy to measure?)

Is the ratio of turns squared (by the way math wise [31/11]^2 is the same as 31^2/11^2) accurate?

I know the torrid size is not critical but the material is for freq response. The way you wrap the Prim/Sec also affects it?

Thanks George

Of course, it is an approximation of reality based on the
ideal transformer assumptions of perfect magnetic coupling
of the turns and an infinite parallel inductance. but, in
reality, if the balun is well arranged on core material that
has good permeability and low losses in the frequency band
of interest, these can be pretty good approximations. Well
coupled turns have an inductance proportional to the turns
squared. Well coupled turns also share the same volts per
turn and two different well coupled windings share the same
ampere turns total. Those are the effects that cause the
impedance reflected through an ideal balun (or transformer)
to have a turns squared ratio. Less than perfectly coupled
turns have a lower power impedance ratio.

> I just copied a design off the web that was measured or reported to

Again, the ratio should always be labeled as an impedance
ratio (somewhat hypothetical in the absence of accurate
measurement) or a turns ratio (pretty accurate if you can
count the turns).

If you have a setup that can excite the device while it is
loaded with a known load (a low inductance resistor, for
instance), while measuring the voltage applied and the
current through its input, you can calculate the impedance.
I think the lab equipment that does this is a vector
impedance meter. Of course, this measurement varies with
frequency, so a bunch of points over a range of frequency is

needed to really quantify its performance for anything other
than single frequency operation. It is also useful to
measure its impedance with the other end both open and short
circuited.

> Is the ratio of turns squared (by the way math wise [31/11]^2 is the
> same as 31^2/11^2) accurate?

Only if the turns are well coupled, magnetically.

> I know the torrid size is not critical but the material is for freq
> response.

You generally want to use the highest permeability material
that does not have losses so high that they look like a
significant parallel load across the balun. Higher
permeability implies higher coupling, and higher inductance
in parallel with the transformed impedance, all other things
being equal.

> The way you wrap the Prim/Sec also affects it?

Yes, you have to be concerned with the stray capacitance
both across each winding, and between the turns of different
windings. details count, especially if you are pushing the
high frequency end of the balun's capability. Best winding
form at the high frequency end makes use of transmission
line effects (electric and magnetic field waves along the
wire length) in addition to just bulk magnetic field
coupling. But at the low frequency end core permeability
and turns squared dominate all other effects.

So, a good balun design begins with a set or requirements
for frequency band (both ends set limits on choices) and the
impedances needed on both sides.

Here is one to have fun with......

After configuring my towers and all, I find I have four points with pulleys installed 200 feet apart and 145 feet in the air.....just
about an 800 foot square in the open....

One tower is only 60 feet away from the shack if the antenna were fed at a rear corner.

The wire can be tilted in any direction.....or fed from any spot, any side.....

I want this for 80 meters primary, 40 secondary.

Idea's...??

Thanks,

-Bill

Go for it!, It sounds good there. I saw your website you sure have alot of equipment even minidisc recorders I wish I had. My minidisc portable recorder is broken and I need $50.00 to get it fixed at radio shack.

Good Luck!

Adam E.

Bill,

Have you done some modeling yet with EZNEC or equal??

I have four hoist points, one at 100' and three at about 65' that will just about handle a full wave loop for 160m.

A great NVIS on 160, starting to get some 'legs' on 80 and much better on 40.

Mine is down at present in favor of a double-L for 160/80 utilizing the 100' hoist point.

I may try something again in the future. Modeling saved a lot of work!! I am going to set that arrangement of yours up just to see how good it will be!!

Very nice 'shack' btw!!

Roger ....Thanks For The reply.....

No EZNEC is a good idea, if you get a chance drop the figures in and see what happens...

Yes .. I retired about a year and a half ago, and I am redoing the shach as I always dreamerd about a but never had the time with businesss/family and the likes....but your seeing a 85% completion on the shack....Now whilr the weather is good efforts are turned to antenna's, Im good on HAFTA for the high bands but have work to do on the high ones...thus the 800 foot loop.....

Thanks,

-Bill

5403. Re: [loopantennas] An Inexpensive Alternative to the WL1030

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-07-17 20:28:20 UTC
From: Chris Trask
Topic: 5388 Message: 5403

Since I first posted this less than a week ago, I have continued working on this active loop antenna amplifier and have made a couple of imrovements. One is the use of a narrower PC board so that the assembly will fit snugly inside 1 1/4" PVC pipe. The second is the reconfiguation of two transformers and the addition of one transistor, the result being a 6dB increase in gain. The particulars can be downloaded at:

http://tinyurl.com/5zeewv

This series of wideband amplifiers does not have the noise and gain performance of my remotely tuned loop, but they do suffice as an inexpensive alternative to the WL1030. I will have a more detailed description of this last version plus a companion biasing tee in a few weeks.

Oh, I wouldn't hold things up just for that. It's nothing more than a
1:1 transformer, a couple of capacitors, and a fuse.

I Have A Miracle Ducker TL Antenna

I purchased it from Universal Radio. It has never been used.

http://www.universal-radio.com/CATALOG/hamantht/5046.html

I'm willing to let it go for $100 + shipping. USA only.

If interested contact me off line.

Tom S

From: Chris Trask
Topic: 5404 Message: 5408

Haven't gotten to that point yet. I've been looking at other alternatives, trying to find the best circuit for this appliction before doing any in-depth testing. So far, that last one has the best performance in terms of audible noise and IMD products. Since you've pointed it out, this might be a good time to do the OIP2 and OIP3 measurements as I've narrowed down the circuitry choices.

I'm contemplating adding the active augmentation transistors to that circuit, as they would improve both the noise and the IMD performance. It would, however, make the circuit a bit more complex and possibly discourage some people from taking it out for a spin. Adding those would increase the cost by about $0.50.

One thing I tried was including active negative inductors to overcome the high inductance of the loop itself. It proved to suffer from both high noise and poor IMD performance. It did, however, normalize the gain. Loops seem to work best when they are terminated with a low impedance, such as a bipolar transistor emitter. Doing so at least retains the nice deep radiation pattern null.

Chris,
What is the frequency range? All the parts look like they are good for
HF. What would be needed to improve performance from 10 to 500 kHz?

From: Chris Trask
Topic: 5388 Message: 5410

The frequency range depends on the size of the loop. For 1 turn and 1M diameter, the first parallel resonance is around 18 MHz, so the antenna is usable up to 15 MHz. I'm using a 64cm diameter loop of #6 AWG copper wire for these experiments, which makes it usable up to 20 MHz.

For 500 kHz, you could use 4-5 turns and 1M diameter, with the turns spaced 4-5 wire diameters apart to avoid excessive interwinding capacitance, which would lower the first parallel resonance.

Gosh Bill, you have it all backwards....antenna work is supposed to be done in the dead
of winter with a 40watt soldering pencil!!!

Sounds like you are having a great time getting everything set up. I have been at
this hobby since 1964 and finally have a desk set-up just for radio!

I got some ideas out of the IKEA catalog and rolled my own.

My place of work is just three blocks from home so I can do a little antenna work at
lunch times.

With your tower and spacing set up....wow....I would be trying a pair of Lazy-H antennas, 90 degrees
to each other, wire beams, vertical loops with a reflector (quad!) sterba curtain, bruce array, etc!!

I have used the Lazy-H and Sterba curtain but they were for 20m and up. You definitely have room
for the 80/40m models and even 160. Gain antennas with a low take-off angle.

I fed mine with homemade open wire line and some commercial ladder line and a balanced tuner.

I may be preaching to the choir here but ON4UN has a great antenna book.

There is also a sloper array where the unused sloper elements act as reflectors for a multi-directional
array switch selected from the shack.

The possibilities are endless!! My difficulty has been with the bands so poor as of late, it is hard to evaluate
a particular antenna on a short term basis.

You could explore the 'diversity reception' idea with differing antenna polarization.

Have you come across the antennex website? http://www.antennex.com/

Back to the modeling, the 800 foot loop on 160 radiates straight up! on 80 about 70 degrees up off the horizon.

Good thing you are now retired!!.

Have fun and be safe!!!

I thought that a high loop inductuance helps to get all loop current (the loop current and loop inductance are placed in parallel, like a norton equivalent circuit) into the low impedance of the amplifier to which the loop is connected, right ?

Thanks For The Return, Roger.....

Right, all kinds of good stuff can go between the four 145 foot points...I just modeled a full 800/793 ' Skyloop...I was not impressed.....

But I'll add your idea's to my list w hich at this point is small....

Have a great weekend...

-Bill

I've been going back and forth between the Norton (current source) and Thevenin (voltage source) equivalents of the lumped element circuit model of the loop antenna. And yes, it should be just as you've said. However, when I designed my series-tuned active loop I used the Thevenin model, and that has proven to be more useful. I've stayed with that perspective since then as it's easier to mentally conceive matching networks.

>

I just completed doing that series of tests, and make a slight circuit modification in the process. In the schematics, the 200-ohm emitter resistors are now 68-ohms, which has each side of the circuit drawing 25mA. At this current level, the OIP3 is +32.5dBm and the OIP2 is +60dBm. Not bad for something this simple and inexpensive.

I don't care much for drawing this much current through the 2N2222, but the power dissipation of the input devices (Q1 and Q2) is still below 0.06W at this level. I might consider something heftier for the output devices (Q3 and Q4), such as the 2N5109. The 2N2222 is still best suited for the input devices in terms of ninearity, but the 2N5109 may have some advantage in terms of noise.

Just read this and was interested to see the results. Only a couple of comments on this test though....

1. I am not sure what was meant by the comment "Using the S-meter was better. I ran all of them through a 30:1 balun."

The TG34 has an output impedance of approx 50 Ohms so why would you put it into an impedance transformer ? (30:1 is one heck of an impedance change)

2. Why was the S-Meter the measurement tool of choice ? An S-Meter does not deliver a Signal to Noise ratio indication. It is well known that Loops, active or passive, often produce less Signal strength but that really is not the point. The signal to noise ratio is the key performance indicator, provided the loop produces enough RF output to overcome the noise floor of the receiver. Most modern HF receivers are quiet enough and have enough AGC range to cope with the low RF output of a decent loop. It is also worth noting that the Ten-Tec is "hobbled" on frequencies below 2 MHz as a feature of it's design
so sensitivity is greatly reduced (I own an RX320 as well)

Jut some food for thought and don't forget that when comparing a long wire aerial (antenna) with a loop, you are comparing E field and an H field aerials ..... they behave totally differently when placed in noisy (i.e domestic) RF environments ;-)

Best Wishes

Fraser

Hi David and the Loop Group,

I've been running an 80 meter, horizontal, loop for a year. It is made from a discarded inverted V. See:
http://ph.groups.yahoo.com/group/loopantennas/photos/view/199f?b=2
and
http://ph.groups.yahoo.com/group/loopantennas/photos/view/199f?b=3
for a more detailed look at the ATR-30 tuner I use to easily match the loop to my transmitter on 80 through 10 meters.

I use only fiberglass or wood supports. No metal!

My feedline is entirely low loss, 450 ohm ladder line and yes I do use the 1:1, 3 core, balun inside the tuner with no problems at all.

My best DX contact with the one turn loop antenna is New Zealand on 75 meters. Not bad for a 30 to 40 feet high and 250 feet long loop antenna.

If you are short of room, you might want to try my compact, three turn loop design at:
http://ph.groups.yahoo.com/group/loopantennas/photos/view/199f?b=5

Cheers.

Hi David and the Group,

The best heavy duty, fiberglass, push up poles for loops
are made by Max Gain Systems. The MK-8 is their tallest
telescoping mast at 43 feet.

The very top section is a bit weak, so I retract it and extend
the mast from the bottom with a Max Gain, fiberglass, 1 3/4" X 8' tube.

MFJ sells the same mast called an MFJ-1908, but it costs more.

See http://www.mgs4u.com/fiberglass-push-up-mast.htm

Best regards.

Hi David,

The height above the ground for a loop antenna depends on its polarization. The so-called "sky wire", whose plane is parallel to the ground, must indeed be up 1/2 wavelength to be effective for long distance (vs NVIS) contacts, similar to a dipole. However, a loop whose plane is perpendicular to the ground works well even with the lower horizontal part very close to the ground. The "sky-wire" is omni-directional like a vertical antenna, while the second loop is bidirectional with a figure 8 pattern (peaks are perpendicular to the plane of the loop) with deep nulls off the ends. Ground losses are minimal because the predominant field is magnetic, not electric.

For your setup you could erect a rectangular loop with the the horizontal ends of the top and bottom horizontal sections attached to two vertical posts a suitable distance apart. Or, using a triangular configuration with one pole, the apex of the loop would be at the top of the pole with the base perhaps 6 feet off the ground on each side. This is called a delta loop.

You might want to Google "loop antenna". There are plenty of sites.

Have you considered a vertical antenna? Easier to erect, omnidirectional.

Good luck,

Dave

*Please do not cut and past whole post *

Hi Richard:

I don't follow your question. Also PLEASE no need to cut and past
whole post, especially my overly long ones, :)

You say TenTec 320? I use a nice random wire about 15' off the ground
about 50 feet long through a 9:1 balun. Works great.

I like the Wellbrook loops but they cost a lot.
http://www.wellbrook.uk.com/ALA1530.html

What band are you targeting? If you want from 100-30,000 than
something like the wellbrook. So you want to make one?

More info needed.

What does TV antenna have to do with it?

Cheers
George

Back in message #3411,
http://groups.yahoo.com/group/loopantennas/messages/3411
I showed that if the loop is terminated in a resistance which is less than
the inductive reactance, then the power which can be extracted from the loop is
proportional to the inverse of the square of the inductance. Hence the lower
the inductance the more power you can extract from the loop.

If you want to keep the low frequency cut off frequency the same you then
need to reduce the teminating resistance, which might not be easy to do.

Forster, in his patent GB 2,235,337, showed a loop being made up as a series
of segments to reduce the loop inductance. According to the UK patent office,
the patent has now ceased.

The amount of mismatch which is desirable between the loop depends upon the
frequency in question, the atmospheric noise, and the receiver noise factor.
Somewhere I have an interesting paper by Sosin on the subject. The way I look
at the matching issue is to consider the power attenuation at the input to the
amplifier, ie:
Actual power input, divided by the power which could be extracted assuming
a perfectly matched and lossless antenna.

I saw Chris's comments re the matching technique for short dipoles developed
by some Russians. The input impedance of a short dipole varies with the

square of the frequency, whereas the input impedance of a small loop varies as the fourth power of the frequency. This could add to the challenge. However with a small loop at low frequencies, you might consider the ohmic losses, which might make the task less onerous.

Chris's desigb is very interesting. Chris - have you measured the input impedance?

If you should find that Sosin paper, let me know. I don't show that as being in my files here.

Trying to devise a dual of the Russian matching network for a loop proved to be unrewarding, at best. I looked at a number of passive matching techniques, as well as using active negative inductors. That last one normalized the voltage gain, but it was far too noisy to be of any value other than a demonstration of using a negative impedance converter.

I've been testing this amplifier exhaustively over the weekend, looking for opportunities to improve the performance. So far, I have the OIP3 up to +39.5dBm, and it was mostly a matter of increasing the bias current to 35mA per side. Some linearity improvement was found by adding a small resistor to each input transistor emitter, and that needs to be looked into further after some low value resistors arrive in the next couple of days. Resistors were also added to the output device emitters to improve the bias current balance of that stage.

The 2N2222 is proving to be a real champion in this design. I have tried the 2N3866 and 2N5109, and found virtually no improvement in OIP3 or noise. That plus they did not like the low impedances together with the transformer leakage inductances, and tended to break into oscillation. Power dissipation in the output devices was a bit of a concern (0.245W), but it's well within the TO-92 device maximum (0.625W) and even more so with the TO-18 package (0.8W). The margin can be improved by adding a heat radiator to the TO-18 package, bringing the ambient maximum up to about 1.0-1.2W. The 2N2219 is essentially a 2N2222 in a TO-39 package, and that can be used as well and there's a good variety of slip-on heat sinks for that package. With the 2N2222 working so well and costing so little ($0.05), why bother with devices that cost around $2 with little or no performance improvement?

BTW: Do NOT substitute the 2N2222A or 2N2219A for these devices as their maximum dissipation is only half that of the 2N2222 and/or 2N2219.

The amplifier input impedance is very small, thanks in no small part to the effects of using passive augmentation. According to PSpice, the input impedance is about 0.20 ohms for each side, which is a good match for a loop. It's difficult to measure this to an agreeable degree of accuracy due to the small value, but looking at the test results I can say that there's a reasonably good agreement with the PSpice simulation.

Total parts costs is still in the vicinity of $30. We keep making it better, not more expensive.

5427. Inkjet printing of resist onto copper to make printed circuit boards

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-07-23 18:08:48 UTC
From: Steve Greenfield
Topic: 5427 Message: 5427

Although this is on topic for the Homebrew_PCBs list, this is going to cover a very -broad- area of hardware, firmware, software, inks, printhead driving signals, etc. So with that in mind, I've created the Inkjet_PCB_Construction group. Volkan, and everyone else involved or interested in modifying or building such a beast, I hope you'll join there.

http://tech.groups.yahoo.com/group/Inkjet_PCB_Construction/

Monthly Reminder for the Inkjet_PCB_Construction group, please read:

Messages and threads:
Please do NOT start a new thread by replying to another message. Even if you change the subject line completely and trim all the original messages off, there is information in the hidden header that Yahoogroups detects and then lists it as if it were part of that thread. To start a new thread, start a new message to the list address.
Inkjet_PCB_Construction@yahoogroups.com

On Topic vs off topic:
The list is meant to be quite specific to the subject of inkjet printing resist directly onto copper for acid etching. However, within that is a very broad area covering modification of existing printers, printhead/printer selection, ink selection, design and construction of flatbed plotters, proper drive to inkjet printheads, firmware, software, baking/post-processing of resist, suitable acids/temperatures, etc. So I ask that any questions or comments whose purpose is not strictly on topic to take place off the list or on another more suitable list.
General electronics questions not related to the above should go to the Electronics_101 list:
http://groups.yahoo.com/group/Electronics_101
For other topics about making printed circuit boards such as toner transfer, photosensitive boards, scratch 'n etch, etc. please join the Homebrew_PCBs list:
http://groups.yahoo.com/group/Homebrew_PCBs/

Subject lines:
Remember to change the subject line if you are straying from the original thread. Please change the subject line if you are on digest, as "Digest 1044" means nothing to anyone. If you are on digest, I suggest changing yourself to "new and improved" so you can more easily reply to individual messages.
If you want an answer to a question, use a descriptive subject line. "Help Me" is bad subject line. "Will my Canon BJC 3000 work?" is a better subject line.
Subject lines affect whether or not people even read your message, and affect people searching the archives for help at a later date.

Trim messages- especially if you are receiving messages in digest form. By the same token, quote enough so we know what you are responding to. "Yeah, I agree" means nothing if no one knows who you are answering or what you are agreeing with. And it is just irritating if it is added to an untrimmed huge long quoted message(s).

Uploading files and photos:
Please use the Description field. Think of a future member finding this, and put enough description so they'll know why it is on the Homebrew_PCBs list out of context of any messages you may have posted about it. Examples: "Test with HP pigmented black ink #15 cartridge baked at 240F for 5 minutes" is good, "My latest project" is bad. I may at any time delete files and photos with insufficient description.

Remember to check the Links and Files if you have questions, you may find the answer there already. Don't be shy about asking, but keep in mind people are more likely to be helpful if they feel you've done some homework before asking. "What is a printed circuit board?" shows you didn't even try, but "I have an HP inkjet printer, will its black printheads work for resist printing?" shows you have put some effort in first.

Do not send "unsubscribe" messages to the list. Either send an email to "Inkjet_PCB_Construction-unsubscribe@yahoogroups.com" or log onto your groups at http://groups.yahoo.com/mygroups to edit your groups. If you are unable to unsubscribe following these instructions, email the listowner at Inkjet_PCB_Construction-owner@yahoogroups.com

Please do -not- post virus warnings. This has been hashed to death on this list and others. If we want to hear about soccer, we'll sign up on a soccer list, if we want to hear about virii we'll sign up on a virus list. Sports, religion, and politics are OFF TOPIC for the list, feelings run high and it is too easy for a passing comment to flare up into a flame war.

Suggestions, recommendations and such, to and from professionals and companies are welcome. If you are posting for your own business, please limit ads to once a month and feel free to post your site in the Links area. Company representatives are encouraged to respond to legit requests for information as long as you identify your connection. IE, don't pretend to be an unconnected customer, there are enough savvy people here that you'll be found out quickly. Just use common sense about replying or people might think you are flogging your business.

Spam- Spammers will be treated with all the respect they deserve. Off Topic sale ads, links, uploads, etc. will be treated as spam and may result in your removal from the list and banning from every other list I am listowner or moderator of.

Thank you,
Steve Greenfield
listowner Homebrew_PCBs, Inkjet_PCB_Construction, and Electronics_101

5428. 5gang Vari-Cap with a Loop, need help.

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-07-23 19:58:34 UTC
From: cqdx5nn
Topic: 5428 Message: 5428

I have a 5gang(see NOTE)air Vari-Cap I removed from a radio that was broke, and not fixable.

I do not know the capacitance of it, and have no way to test it, it works, and I have tested it with a loop antenna, but need to know if I should tie all the gangs together, or use different coils(turns or wire) on each gang?

Im using it with am Icom R75, for the MW band, use a single turn of wire in the middle, being feed with coax.
The reason I am using this 5gang cap is because its the toughFFF-est one I could find. I will taking this loop with me everywhere.

Or could I use some resistors, coils, other caps, etc, on the bigger gangs?

Any help and comments are appreciated.

NOTE: 2 gangs have 13 plates, 3 gangs have 3 plates.

Thank you

Topic: 5428 Message: 5429

I could be wrong but your capacitor is probably for a MW/FM set whose FM section had an RF amp, while the MW section didn't. Not sure what your loop configuration is, but the two larger sections wired together may provide you the correct capacitance. Refer to links found in this reflector for the correct size and number of turns.

>

It's a nice, simple solution. However, since the amplifier has a high input impedance, the pattern null will be deteriorated and you will defeat most of the electric field immunity. It does, however, relieve you of having to provide an impedance match or series tuning into a low impedance amplifier, such as common-base.

An even better transistor for this would be the BFQ19, which has better noise and linearity characteristis than the 2N3866 and which is less expensive and more readily available.

From: deju5us
Topic: 5431 Message: 5433

Hi there ... I am normally a bit of a lurker, but have actually built this up a couple of days ago using BC338s. It works quite well and I am pleased with the results so far. Regarding degradation of the nulls, they are not as sharp as I would have wished but I do have it working on 30m of coax at the moment and I am sure there is common mode pickup there. Maybe feeding it with a separate power feed and using a balanced feeder will improve matters.

For those wishing to try something else, I have had success with an active antenna kit fed from a single small turn made of RG213 via a matching transformer wound on a ferrite core. The RG213 was fed through the core and the ends soldered together to make a single turn.The coupling winding had 15 turns on it. Any more and I had overloading issues from my local BCB station. Will search out and post the link to the site where I found the idea later.

Regards, John S.

Johan-Fredrik,
I must aplogize for that photo. I used that one to illustrate the final physical size of the design, and I should probably replace it with a photo of the larger board with the final transistor and transformer arrangement. I'll take care of that tomorrow when I have better light. I have since disassembled the amplifier in that photo to use the board and coupling transformer in a subsequent design.

Transformers T4 and T5 are both 1:1:1 ratio components made with 4 turns of #32 trifilar wire (three wires twisted together) on a Fair-Rite 2843002402 core. Transformers T2 and T3 are also 1:1:1 trifilar constructs, where two windings are connected in series to arrive at the 2:1 ratio. I design my transformers using 1:1 bifilar and 1:1:1 trifilar windings so as to get better coupling and lower leakage inductance.

BTW; I have a working prototype of Amplifier #3 with a matching network between the antenna and the first amplifier that improves the high-end gain by 15-20dB. I've also added an additional transformer identical to T4 where the end wires are connected to the antenna and the inner connections go to the amplifier. This provides an additional 9.5dB of gain. It needs a bit more work to bring it to final form.

Chris, thank you for your swift reply.

On page 3 in the PDF document you write:

"Supply voltage is 12V and is provided by way of the coaxial cable that goes to a bias tee and then the receiver"

Why not use a LM78L06 instead of the LM78L05?

In my home country (4,7 million people and less than 4500 Hams) the Communications Concepts RF800-0 Balune Core is next to impossible to obtain, so I have to make on for my self with to beads with core material 43, some thin plated copper tubing and two pieces of PCB. I just finished building the amplifier and when the last to parts for the balune core arrives I start testing it. Later I will try to use the amplifier connected to a balanced feeding loop on a tuned 1 Meter (0.5 inch) copper loop.

In the overall scheme of things, I want to provide as high a collector-emitter voltage on the output devices that I can so as to get the highest P1dB (1dB compression point) which is directly related to both OIP2 and OIP3. The LM78L05 lets me do that with a part that is commonly available almost anywhere.

The RF800-0 and the other balun core assemblies made by Communications Concepts are easily reproduced from ferrite sleeves or toroids, as you've described. You saw in the earlier photos that I was first making a current transformer from powdered iron toroids, brass tubing, and fabricated end plates. The RF800-0 is a common point of reference, and when they are obtainable they are very convenient for all sorts of designs.

Please be kind, rewind... er, please trim when you reply. Many of the list members in Europe must pay for their internet by the minute and long unnecessary messages cost them money. And it makes it very difficult for those of us on digest to read the messages.

So please just take a few seconds to delete what isn't necessary when replying.

Thank you,

5445. Remote tuning

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-07-31 23:18:53 UTC
From: tenorman1952
Topic: 5445 Message: 5445

So, it occurred to me that it would be good to come up with a cheap and easy way to turn a tuning capacitor on a loop that is mounted somewhere outside.

Now this is just an idea... I have flow radio control (aka R/C) model aircraft for many years.

The receiver and servos that operate the control surfaces in the plane run off 4.8 v nicad packs. Actually, they will run on anything from 4.8 v - 6.0 v. So, if power can be sent out to the antenna this could be made to work.

Tuning capacitors rotate 180*. Most servos only rotate 90*, but can be modified to rotate further.

Inside the servo is a feedback potentiometer driven by the output gear of the servo. These pots are usually 10k ohms. By attaching a 4.7 k 1/8 w resistor on each outer terminal of the pot, and connecting those leads to the resistors, the servo will now rotate 180*.

Now a direct connection can be made from the servo's output shaft to the tuner shaft with a piece of rubber or vinyl tubing.

A cheap two channel R/C car/boat radio system can be used for this, under $100.

Just a thought...

Paul C.

Paul,
That's basiclly a good idea and it's probably workable if the 180
degree mod can be done
with a servo powerful enough to turn the cap. The small tuning caps
from cheap radios
are usable in loops and turn easily. But these days remote tuning is
usually done with
a varactor diode. This replaces the cap and is tuned by a DC bias
across it. This variable
voltage is usually sent up the signal feedline, isolated by
capacitors. Other posters on
this forum have given links to examples of this.
The servo would, however, be a good way to rotate the loop. You can
find circuits on the
web to operate the servo directly without the R/C stuff.

Chuck.

I remotely tune my receiving loops with varactors. The tuning voltage is also the amplifier supply voltage, and the amplifier is designed to work with the varying supply voltage.

I'm going to be working on a remotely tuned transmitting loop where the motor is controlled with the DC voltage going up the coax. Using a variable capacitor without a stop pin on the shaft relieves me of the trouble of having to add stop switches and diodes.

From: tenorman1952
Topic: 5445 Message: 5448

I received a good follow up question from one of the members.

"Do servos need a continuous pulse stream to maintain a position?"

No, but if you just turn off the transmitter, the momentary drop in voltage distorts the pulses just enough to make the servos jump a bit, often as much as 15*-20* off their original position. (I'm using * for degree)

With a wheel type car/boat transmitter, the centering spring would have to be removed from the steering wheel. With a "two stick" transmitter, such as used with gliders, the centering spring would be removed from one stick, and set so it will stick in position, such as used for a throttle. This is easy to do.

http://www3.towerhobbies.com/cgi-bin/wti0001p?&I=LXARP0**&P=7

If you have 12 v going out to the antenna, such as to operate an active antenna, you could come off the 12 v with a 7805 (5v) or 7806 (6v) regulator chip (TO-220 type) with a capacitor accross in and out legs to ground. I've done this with R/C gear run with higher voltage battery packs used for electric boats and with an electric powered glider. A receiver only draws about 50-80 ma, and servos draw about 50 ma at idle, and 100-200 ma moving, so this won't tax a 7805 at all, which will put out 1 amp easily. And a tuning cap has almost no resistance, so, moving the servo won't draw but about 80-100 ma.

I may be wrong on the resistors added... if the pot is 5k, use 2.2 k resistors on each side. If 10 k, use 4.7 k on each side. The feedback pot is simply a voltage divider.

The way a servo works, input pulse is stretched, and turned into a voltage. Longer the pulse, the longer the voltage. The servo circuit compares the pulse/voltage with the voltage on the feedback pot via an op amp. If one voltage is higher than the other, the op amp produces a + or - voltage, which drives the motor one way or the other until once again the two voltages are equal. So, doubling the resistance of that feedback pot will double the throw of the servo from 90* to 180*, which is the rotation of the tuning cap. Putting a resistor on each end of the feedback pot will keep it approximately centered.

Stick movement to servo movement is very precise and repeatable, otherwise it wouldn't make a good aircraft or whatever control.

Now, here's another possibility...

Instead of the whole receiver/servo in the antenna... just a servo and supply it with 5v to operate. No radio, but control it with a servo tester, which is just a little box with a knob and a battery. You would probably have to use an optocoupler or op amp buffer due to the long line.

http://www3.towerhobbies.com/cgi-bin/wti0001p?&I=LXVK79&P=ML

http://www3.towerhobbies.com/cgi-bin/wti0001p?&I=LXUK84&P=ML

So, no tx, no rx, just 5v for the servo tester, 5v for the servo. See the leads? Black is common or -, red is 5v, white is signal (or pulse). It would be easy to put an op amp buffer inline.

In a second email he commented:

"I asked the question as I was concerned in case the servo needed a continuous pulse stream. As you would be sending LF square waves out to control the servo I was thinking of any possible broadband interference that might result."

I replied:

That is valid a concern.

If the pulses are cut off cleanly, that is, just turn off the white signal wire, the servo stays in the last position. If the transmitter is turned off, as the voltage falls, the servos jump.

You are correct... a "sail control" servo, as used in R/C sailboats
would be more appropriate for rotating the loop.

And as I just posted about a controller:

http://www3.towerhobbies.com/cgi-bin/wti0001p?&I=LXVK79&P=ML

Sail wench servo.

http://www3.towerhobbies.com/cgi-bin/wti0001p?&I=LXGZU3&P=7

Hi Paul,

Yes it can be done. Whether you use a wire connection or a wireless connection (R/C) ... the problems are mechanical in nature. I have seen some locals using remote control of the variable capacitor and the problem they had was slowing the servo motor sufficiently for smooth tuning. Often disabling switches are used at either end of the variable rotation. It is really the only way to go if you are using the loop to carry any significant power. A receive only loop is best tuned remotely with varactor diodes.

Jim, VE3CI

5451. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-01 22:17:29 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 5451

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.
http://members.cts.com/king/j/jlkolb/site/dif_fet.pdf

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

5453. Multi turn transmitting loop questions...

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-02 00:43:05 UTC
From: David
Topic: 5453 Message: 5453

Hi, I'm about to build a transmitting loop, ~ 8M circumference, for 80-40-30 metres.

I have some 1" heliax, and a supply of 3/4" copper pipe to work with.

I have several Jennings UCS300-15S caps, and a few HV doorknob caps.

I also have several ~12VDC low RPM (geared) motors.

I have done the calculations a few different ways, used the calculators and spreadsheets that others have provided, modeled in nec and I think I have the right arrangement of parts and materials.

I have come up with a bunch of pieces of scrap lexan from the bin at the local plastic supply house, so I have made some pillow clamps,housings and mounting stuff from it.

I believe there is enough material to make several antennas, so the thought occurred to me; why don't I try a two turn loop, of approximately the same circumference (8m x2) and see if I can get it to resonate on 160 & 80M? (the space I have to put it in is limited to this)

I am assuming that the driven loop will be twice the size of that in it's one turn sibling. I am guessing that the final ratio still needs to be 1/5 for the impedance match. If my logic is faulty, please let me know what the right idea is.....

My question is, and there seems to be a lot of conflicting opinions out there, is will it be worth the trouble? Has anyone done this and made measurements that support the multi turn design or is it just a fool's errand?

Thanks,

David

David,

In my view, experimenting with antennas is one of the few areas left to us where we can have fun.

I was looking for something to use for portable working, and have plagiarised SGC's "Stealth" product. Mine is a four-turn square loop about 5' on a side tuned by an SGC237 autotuner close to one corner. Results so far are encouraging, if not spectacular, but the simple construction has not wasted time or materials it it all comes to nought.

Modelling and measurements are all very rigorous, but will it work in practice? Build it and see. AND have fun.

73s, Mike M0DVO

This assumption will not work.

Th radiation resistance of a multi-turn loop rises exponentially with increasing number of turns. Hence it is possible to make a multi-turn loop for a single band which has near 50 ohm input impedance. The math is in Kraus: Antennas. McGraw Hill, 1950, chapter 6, section 6-8.

You need to measure the input Z with an antenna analyzer, as the one I built had a reasonable radiation resistance (?25 ohms) but had capacitative reactance, requiring a coil in parallel with several loop turns. For such a loop your capacitors will not work.

Hi David,

Some interesting questions for which I do not have answers ... just opinions. The advantage and the disadvantage of the small (1/10 wavelength) single turn loop is it's Hi-Q. When resonant and properly coupled it provides amazing performance in restrictive space. At the same time the disadvantage is its narrow band-pass and the demands put upon components due to resultant hi RF voltages. The common feed method for the small tuned loop is as you point out a small driven loop approximately 1/5 the size of the tuned loop which seems to provide the proper coupling.

I have tried multi-turn wire loops with a similar circumference, 2 and 3 turn and found the performance dramatically different. The Q is much lower ... Perhaps if I had constructed the multi-turn loop with copper pipe instead of #12 wire. The only way I could achieve sufficient coupling was to place a link coupled balanced antenna tuner right at the loop and used a noise bridge to tune the coupler. It worked well on 40m but was not very dramatic. 80m was mediocre.

As the length of the loop gets longer ... eg 2 turns at 8m ... it appears that inductive coupling becomes less effective and direct link coupling more effective.

Jim

Hi and thanks to all for the replies.

I agree with everyone so far (and our local loop guru VE2CV) that the single turn very mall loop is the optimal choice.

I have built one already, which is a 1M diameter loop, for comparison against the MFJ1688 I picked up on eBay a couple of years ago. As you might expect, the home brew copper loop, even though it is a smaller diameter, beats the aluminum.

There are really just a few design considerations didn't mention and those are the classical ones: size, mass and cost. (and of course these are multiplied by the Wife Approval Factor)

I have an area of about ~5 metres to work with. I'd like them to be small enough that I can rotate the two loops (swing 'em round 90 would be more accurate)

It would be nice if the snow and ice won't rip them apart (we had 14 feet of snow in the yard last winter). So it needs to be strong and not have a larger span than is prudent for the pipe diameter.

I went to the local plumbing jobber supplier yesterday, inquiring about the cost of various diameter copper.
66 ft spools of type K were:
3/4" = ~$300
1 " = ~$750
1 1/2" = $1300
2" only in 12 ft sections at ~$200 each.
Larger copper pipe by special order..... and special price!

Type L is a bit cheaper, but as I recall it has a higher resistance, which is counterproductive for us....
I have on hand 16M of straight Type K 3/4", which I have already cut for an octagonal loop with 1 M segments. So, I will assemble that one shortly.

As I said, I have acquired plenty of spare parts for this, and I'd really like to see how the continuous copper will add to the efficiency. On paper it is undeniable so I am eager to test the on air results.

Since the copper is so expensive, I should opt for the coil of 3/4", based on my remaining budget.
Unfortunately, I don't' think the 3/4" will be strong enough for the 160 M loop, which has the diameter of ~5M. This is also too large for the space I have, so it is moot, really.

This was why I thought the multi turn might be practical for me. I read an interesting account of a multi turn experiment on Antennex by Anselmo Stiffan, IZ3BGJ.
His results were:
"Its performances when operated at 1.5 meters above ground against a 1/2-wave dipole at 12 meters above ground were approximately:
* -22dB on 160m band
* -18dB on 80m band
* -9dB on 40m band
* -3dB on 20m band
The bandwidth at SWR=2:1, which is a good indicator of the antenna Q factor and hence its efficiency was:
* 1.6 kHz on 160m
* 2.5 kHz on 80m
* 6.4 kHz on 40m
* 23 kHz on 20m
"
He seemed to get it to work, so that is why I went fishing for other opinions.

I haven't convinced myself yet that it is worth several hundred extra dollars to see if a two turn loop for 160 will work.

Whatever I end up with, I'll post the results.

--- In loopantennas@yahoogroups.com, "David" <va3ae@...> wrote:

My comments above were for a loop for 20 meter. It was about 4 feet on a side. I recall it had 4 turns which were spaced maybe 2 feet apart from each other but were essentially made with a single continuous length of 12 gauge wire. The dimensions above were chosen for a reasonable direct match to a standard tranceiver (50 ohms). This is not a small loop. As stated above, its radiation resistance was on the order of 50 ohms (not milliohms and not 25 ohms as stated above) with capacitative, not inductive reactance as would be seen in a small loop, so it requiring a coil, not a capacitor for cancelling reactance. The formulas are in the Kraus reference. It can be designed for any band using the formulas.

5465. AM antenna suggestions for use in an attic?

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-05 00:23:51 UTC
From: Zack
Topic: 5465 Message: 5465

I would like to put an AM antenna in my attic and run it to the Sony XDR-F1HD tuner in my living room. Not looking for a DX antenna, just one for local AM listening.

Can anyone suggest where I could get plans to make something like this? A simple loop antenna that would cover 540-1600 khz and fed via 75 ohm coax?

Really cannot use one that has to be retuned for different frequencies.

Thanks
Zack

I've used a loop of about 10ft of wire with a coax or twisted wire
leadin - but it usually needs to be very short - like hanging in back of
the tuner. Also a shorted loop of coax works as well.

Hi,

I have an AM tuner which came with a loop for local reception. It is a simple untuned unit consisting of 5 close wound turns on a light plastic form 8 1/2 in in diameter. It uses a twisted pair of wire as a feed line ... coax would work as well. It is simply a matter of orienting it for best reception. I would think any physical design ... perhaps larger in diameter ... with 5 to 8 turns ... strategically located in the attic would work well.

Jim

You don't like the small loop that was included? It's actually not bad.

> Can anyone suggest where I could get plans to make something like this?
> A simple loop antenna that would cover 540-1600 khz and fed via 75 ohm

I see two issues here. First, a loop is going to be directional, so you'd have to turn it for best reception. Perhaps most of the stations in your area lie fairly close to a single line so that wouldn't be a huge problem. Or maybe you could use a loop with a low Q so the null regions would be shallow and defuse. That should still work okay for local reception.

Second, I was just reading today that the MW antenna inputs on the XDR-F1HD are balanced. (If you look closely, you'll notice neither of the inputs is marked as ground.) The article said this was one of the reasons the little loop they include rejects noise so well. The balanced input allows it to work almost exclusively in the magnetic domain, rejecting most of those nasty electrical radio wave components that carry the majority of the local noise. I have absolutely no idea if you could accomplish the same kind of thing by going from balanced to unbalanced and back to balanced. I suppose you could always use ladder line instead of coax, staying balanced the whole way.

Nice radio, BTW. I got one last week. Amazing FM reception on that thing. It's too bad they didn't include a way to stay with pure analog reception. I think the analog signal sounds better on most of the local "HD" stations. (I got it because I heard it was an excellent FM DXing radio, not so much for the HD part.)

Maybe I will stick a 300-75 ohm balun on it, run some coax from the attic and put another 75-300 balun to the tuner.

My issue is that the tuner is right under a Sony 36 inch HD TV that puts out a LOT of noise on AM. Hence my wanting to remote it.

It think that I will give the loop a try though!

From: Rob - W1AEX
Topic: 5465 Message: 5471

Hi Zack,

I ran into a similar situation when I picked up my Sony XDR-S3HD and installed it 2 feet away from my router and cable modem. Lots of noise pours out of those network devices all across the AM broadcast band.

What I did was to take two 25 foot lengths of #24 insulated wire and tie one set of ends to a table leg, then stuck the other ends into my cordless drill. I stepped back to put tension on the wires and then ran the drill for several minutes. It did a great job of putting about 5 or 6 turns per inch all the way along the length of wires. I used this as a feedline to place a 10 turn loop (wound around the edges of an old plastic CD case) in a closet about 20 feet away from the router and modem. As someone said previously, the loop is definitely directional, so I oriented it to favor stations north and south of me and it works great. It is noise free and very effective. Best of all, the price was right with a total investment of $0.

The 75 ohm to 300 ohm baluns used for TV coaxial use are very lossy on the AM broadcast band, and using 2 of them would make it even worse. Stick with twisted pair or even TV twinlead and you will have much better results.

Rob W1AEX

Zack: I have built a number of these loops:

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=300246425307

and in the seller's blurb where he mentions this link:

http://www.audioasylum.com/forums/tuner/messages/7246.html

I am the author of that post at Audio Asylum.

These loops are nice kit versions of the "Carver Ultimate AM Loop" as
described here:

http://members.cox.net/rwagoner/columns/am_antenna.html

I have one of these loops on each of my three stereo systems. I also
made one for my brother, my sister, my brother in law for his office
system, and a some for various friends. These antennae work!

You may connect to it with 300 ohm twinlead or 75 ohm coax, or even
just a twisted pair of wires. It IS directional, so you will have to
orient it for best reception of your favorite stations.

But why put it in the attic? It works equally well right by your
stereo system and you can aim it immediately. I have a friend who
uses his in his basement ham shack with good results.

It is important to connect both leads, one to the tuner's AM antenna terminal, the other to the tuner's Ground terminal (or chassis ground).

While this simple untuned loop is not as strong as a tuned loop, it works quite well, and no tuning.

Paul

Thanks a lot!
I purchased through them the simple and cheap rotator. It will be the cheapest way to get it.
No digital screens, just the most needed things. Suits me well.
They have sent me very prompt replies, many of them. Seems very good service!
Thanks again and continue your good attitude.

Hello All,
I made a BCB loop antenna using a 14 inch embroidery hoop with an odd number of pegs and 19 turns of litz wire wound in a basket weave.
I use this with a Grundig S350 to receive a distant station on 1490kc, most days the loop will make it listenable.
The question is, why is it when the loop is tuned just below the desired frequency the signal dips, then peaks when tuned on frequency. This happens all across the band.
Just curious, what is happening here?
Thanks, Herb Dean WA1IBN@...

The terminal impedance of a loop antenna is best seen as a shorted transmission line, which was proposed by Terman and others over a half century ago. At low frequencies, the impedance appears much like an inductance, and then takes on the characteristics of a parallel resonance (high impedance) across the terminals as you approach the point where the apparent height of the loop is a quarter wavelength. This is the point at which you are seeing the signal peak.

At the point where the apparent height of the loop is a half wavelength, the impedance is a series resonance (low impedance) across the terminals. This is the point at which you are seeing the signal dip.

This characteristic of the loop antenna impedance repeats every half wavelength.

BTW: Could you provide us with a photo of this antenna you made? The way you constructed it sounds interesting.

Hi,

That is an interesting observation. The tuned circuit (tuned loop) takes on different impedance characteristics as it approaches resonance. At resonance it takes on a high impedance and drops off sharply on the low side . The drop off is much more gradual on the other side. This is one of the techniques used in multiple tuned circuit crystal sets to separate closely spaced MF stations. The two circuits are inductively coupled with the antenna on one side and the detector on the other. The two tuned circuits are then tweaked to maximize the desired signal and attenuate the undesired signal. I guess you could call it the ultimate pre selector.

I have also used this characteristic (in the old days) with a home brew IF Q-multiplier at 85 khz to provide rejection of undesired CW signals. You could also experience this phenomena when tuning the single xtal IF filter in old receivers. Today, someone trying out one of these old receivers would scoff at these old xtal IF filters ... however in the hands of a skilled operator they can be quite good .... but it was more of an art hi hi.

I am not sure I have a picture of your loop construction. I have constructed circular loops using a circular piece of plywood with pegs mounted around the circumference. Looks like a Crown & Anchor wheel. I then weave the winding on the pegs. However you mention an embroidery hoop ... not sure how you fasten the pegs. It sounds like they would be facing out from the hoop .... eg like the steering wheel on a ship ?

Another technique I have used is to cut slots in a circular piece of plywood ... the slots radiating out to the circumference. I then basket weave around the slots.

Jim

Ooops! I had my wires crossed here a bit. I should have said that the signal null occurs at the frequency where the loop is at it's parallel resonant frequency. The signal peak is the point at where you have the best match between the loop antenna and your receiver. I had my head buried in writing about loop antenna matching networks and should have given my response a bit more thought.

I'm much better now.

Hello All,
For those that asked attached is a picture of my BCB loop.
You can see the tuning capacitor in back mostly open, only one section is used.
Just so happens I have a 1937 issue of Radio Engineering by Terman, I'll look there.

Hi,

I found the picture very informative and interesting ... I have never seen 'basket weave' done this way. In one way it is the same loop as mine ... but i fastened all the dowels by screwing them to a circular disk. It is not clear from the photo ... how do you fasten the dowels to the embroidery hoop ? I assume you drill a hole and pass through a screw of some sort. The weave then takes place on either side of the embroidery hoop.

Jim

Hi Jim

From the photo I would say that the dowels have slots cut in them to fit
over the hoop and then screwed or glued in place, perhaps better the latter as
that would avoid any metal content in the loop support.

If you look closely you will see that the dowels protrude from one side of
the loop only so the weave is also just on one side.

It's certainly an attractive design.

regards

Nigel

5488. horizontal loop tuner

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-13 20:15:47 UTC
From: randy zelick
Topic: 5488 Message: 5488

Hello there,

This is my first post to this group, and apologies in advance if I violate some etiquette due to being a novice.

I am trying to turn a dipole into a horizontal loop antenna to (1) get more wire in the air and (2) reduce a large amount of ambient noise. It has been suggested to me that a loop is worth a try.

The loop cannot be really horizontal, however. It will end up being close to a sloping square. The highest support point will be about 120 feet in a cedar tree, but two legs will then slope down at 90 degrees to supports maybe 35 feet from ground level. From each of these points wires will slope further to a chimney, where I plan to have an outdoor tuner.

So finally, to my question: what tuner?

My first thought was SGC, but even used ones on ebay are well over $300.00. I see that MFJ has a new outdoor tuner (model 927) which is less, but when I called them it looks like you must use a balun on the output of the tuner to drive a loop (or dipole). The MFJ is a unbalanced path from input through to output. I'm not sure the SGC would be different, but perhaps.

Does anyone have experience with the MFJ, and is it likely to work with the balun strategy? If so, then I would most appreciate a hint as to the best sort of balun to use.

I also thought of using ladder line where the loop wires come together, but I don't see a way to route to my hamshack with this feedline. So it is going to be coax to the tuner.

Thanks much for any help,

=Randy=

Hi,

Both tuners .... the SGC and the MFJ are unbalanced to unbalanced ATU ....
SGC would call it a 'coupler'. They are designed to be mounted at the
antenna whether it is a vertical, dipole, or loop. It is an excellent
strategy to build a multi-band antenna. In the case of a balanced antenna
such as a dipole or a loop as you propose it is a simple matter to connect
it at the feed point. The antenna terminal connects to one side of the
loop and the other side of the loop connects to the coupler ground
terminal. I don't recommend putting a balun between the tuner and the
antenna .... as they (baluns) cause more problems than they solve. They
are low impedance devices and work 50 ohm to 50 ohm (1:1) or 50 ohm to 200
ohm (4:1). As soon as you get much higher impedances they become
unpredictable in performance.

Now the only reason to talk 'balun' at all is to prevent as little RF
current to flow on the outside of the coax shield as possible. This can be
easily accomplished by placing a 'current choke' between the coax and the
coupler, 50 ohm to 50 ohm, (the correct place) ... simply coil approx. 20
ft. of the coax cable at the point it goes into the coupler and you should
have an effective current choke.

Many of the SGC couplers are sufficiently weather resistant to sit on their
own ... however it is always a good idea to keep them in a second

protective enclosure. I am not familiar with the MJF-927 ... but I note that they use a different description re weather "weather protected" and not weather proof hi hi.

Ladder line is a good alternative .... and in fact can be used in conjunction with the coupler. For example you can use ladder line between the loop and a convenient place closer to the shack and then 'couple' the balanced line to the coax in the exact manner already described. Then the coax can be routed to the shack. This method is superior to trying to couple balanced line to coax with a balun .... eg the coupler can handle the various impedances much more efficiently than the balun.

Go ahead with your plan and you will have a very good multi-band antenna.

Jim, VE3CI

Hello Randy and the Loop Group.

I've been using an inverted V which has been converted
into a loop. The inverted V has basically been shorted out by
a large 3 sided horizontal piece of wire. The total length
of the resulting loop is 250 feet and 30 to 40 feet high. The tuner
is a manual type, tuned in the shack and provides a flat match
to a 1KW solid state amplifier. The loop antenna can also be
connected to any transceiver or receiver. The antenna transmits
and receives well from 80 to 10 meters.

See:

Randy, as you are of course, an ARRL member, you should have received your Sept QST by now. if not, then within the week. Therein, you will find a review of the MFJ 927. It seems to be favorable for a less than $300 feedpoint autotuner.

you might read that in the course of your decision making

THNX!
Very interesting!
Would you like to tell us more about this unique antenna?
How did you make it? Details, possible drawings etc?
My appreciation, 73 de Ami.

Subject: ***SPAM*** [loopantennas] horizontal loop tuner

Hello there,

This is my first post to this group, and apologies in advance if I violate some etiquette due to being a novice.

I am trying to turn a dipole into a horizontal loop antenna to (1) get more wire in the air and (2) reduce a large amount of ambient noise. It has been suggested to me that a loop is worth a try.

The loop cannot be really horizontal, however. It will end up being close to a sloping square. The highest support point will be about 120 feet in a cedar tree, but two legs will then slope down at 90 degrees to supports maybe 35 feet from ground level. From each of these points wires will slope further to a chimney, where I plan to have an outdoor tuner.

So finally, to my question: what tuner?

My first thought was SGC, but even used ones on ebay are well over $300.00. I see that MFJ has a new outdoor tuner (model 927) which is less, but when I called them it looks like you must use a balun on the output of the tuner to drive a loop (or dipole). The MFJ is a unbalanced path from input through to output. I'm not sure the SGC would be different, but perhaps.

Does anyone have experience with the MFJ, and is it likely to work with the balun strategy? If so, then I would most appreciate a hint as to the best sort of balun to use.

I also thought of using ladder line where the loop wires come together, but I don't see a way to route to my hamshack with this feedline. So it is going to be coax to the tuner.

Thanks much for any help,

=Randy=

5496. Rock Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-15 11:54:30 UTC
From: oh6bi
Topic: 5496 Message: 5496

Hi All

I will very soon make a short one week trip to
Swizerland and I am planning to take my 817 with me.

After reading lot of MagLoop info from the net
I found RockLoop writings. One example:

http://www.qsl.net/dl1gsj/html/rockloop.html

That could be the easy start with MagLoops and it is
light and flexible in the suitcase.

Any opinnions ? Or experience ?

What kind of toroid ? iron or ferrite ?
I have T50-2 ironpowder toroid, I have used that material
for 1:4 balun in QRP tuners.

The photos on that web page just helped me solve a somewhat tricky mechanical problem that I've been struggling with. I had come to a conclusion about wideband matching networks for loops (the documentation is being reviewed), and had dug out another project for a motor-driven tuner for a QRP transmitting loop.

I don't care much for the arrangements with the variable capacitor at the top of the loop, and I'm equally at odds with the gamma-match Mini Loops. Both of these have ungainly mechanical problems that need to be addressed. The coupling transformers that people commonly use are a serious source of loss, and that also needs to be resolved to bring the efficiency up. I have a receive only varactor-tuned version of my idea on my test bench at the moment, and I'm going to toss one of my dual 365pF variables into the box for the transmitting version along with the sketch and notes that I just furiously wrote down.

Just goes to show that nobody has all the solutions.

Too bad we can't make a portable loop where the loop itself can be inflated.

You could use hydrogen and call it the Hindenloop. And yes, if the conducting surface had a sufficient radius to hold enough hydrogen (or helium), then it would rise in the air and give better reception.

Where's that fellow with the flying lawn chair?

Hi Jim,

Thanks for your help, and sorry for the delay in responding. I'll try your idea and see how it goes. Some others who responded seemed to think that a current balun was advisable, so clearly there is not a single view. I suppose you would say that the extra loss in the 20 ft of coax acting as a choke is less problematic than the loss with the balun.

Cheers,

=Randy=

Hi,

Both tuners .... the SGC and the MFJ are unbalanced to unbalanced ATU ....
SGC would call it a 'coupler'. They are designed to be mounted at the
antenna whether it is a vertical, dipole, or loop. It is an excellent
strategy to build a multi-band antenna. In the case of a balanced antenna
such as a dipole or a loop as you propose it is a simple matter to connect
it at the feed point. The antenna terminal connects to one side of the

loop and the other side of the loop connects to the coupler ground terminal. I don't recommend putting a balun between the tuner and the antenna .... as they (baluns) cause more problems than they solve. They are low impedance devices and work 50 ohm to 50 ohm (1:1) or 50 ohm to 200 ohm (4:1). As soon as you get much higher impedances they become unpredictable in performance.

Now the only reason to talk 'balun' at all is to prevent as little RF current to flow on the outside of the coax shield as possible. This can be easily accomplished by placing a 'current choke' between the coax and the coupler, 50 ohm to 50 ohm, (the correct place) ... simply coil approx. 20 ft. of the coax cable at the point it goes into the coupler and you should have an effective current choke.

Many of the SGC couplers are sufficiently weather resistant to sit on their own ... however it is always a good idea to keep them in a second protective enclosure. I am not familiar with the MJF-927 ... but I note that they use a different description re weather "weather protected" and not weather proof hi hi.

Ladder line is a good alternative .... and in fact can be used in conjunction with the coupler. For example you can use ladder line between the loop and a convenient place closer to the shack and then 'couple' the balanced line to the coax in the exact manner already described. Then the coax can be routed to the shack. This method is superior to trying to couple balanced line to coax with a balun .... eg the coupler can handle the various impedances much more efficiently than the balun.

Go ahead with your plan and you will have a very good multi-band antenna.

Jim, VE3CI

5507. Wideband Loop Antenna Matching Networks

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-18 00:59:30 UTC
From: Chris Trask
Topic: 5507 Message: 5507

After quite a bit of work, I've come to a conclusion regarding the practicality of passive wideband matching networks for loop antennas. Basically, the high Q of the loop antenna impedance makes the realization of such matching networks a formidable task. Along the way, I came up with a balanced network section that I cannot find in any textbook that I have here. Despite this, the results of this was disappointing, to say the least. However, I wrote a fairly full description of the approach that I had the most success with, and it's available at:

http://tinyurl.com/5693jc

After I was done with all this, I quickly put together a remotely tuned matching network that uses three transformers and a pair of varactors. It works almost as well as my active loop in the QEX articles, and it's the ground work for a tunable matching network for transmitting loops. I'll have more about this later after I get some parts to reduce it to a final version and iron out a couple of mechanical details. For now, I'm using it in place of my active loop.

Hello Loop Group,

Please see another one of my loop
doodles at:
http://ph.groups.yahoo.com/group/loopantennas/photos/view/199f?b=6

The challenge here would be to isolate any part of the
SGC 2035, 500 watt, coupler from ground to get a
balanced loop.

The advantage of using a coupler is that it can be
tuned remotely from an amateur transceiver.
The coupler is water proof. You can mount it outside
at the antenna feed point, where an antenna tuner should
be.

Cheers.

Hi Chris,

Very interesting. I'd just like to say I enjoy reading your papers and want to thank you for taking the time to share them with the group!

After quite a bit of work, I've come to a conclusion regarding the

practicality of passive wideband matching networks for loop antennas.

Basically, the high Q of the loop antenna impedance makes the realization of

such matching networks a formidable task. Along the way, I came up with a

balanced network section that I cannot find in any textbook that I have

here. Despite this, the results of this was disappointing, to say the

least. However, I wrote a fairly full description of the approach that I

had the most success with, and it's available at:

http://tinyurl. com/5693jc

After I was done with all this, I quickly put together a remotely tuned

matching network that uses three transformers and a pair of varactors. It

works almost as well as my active loop in the QEX articles, and it's the

ground work for a tunable matching network for transmitting loops. I'll

have more about this later after I get some parts to reduce it to a final

version and iron out a couple of mechanical details. For now, I'm using it

in place of my active loop.

Thank you. This one's not over yet. I'm lookng into the possibiity of using the topology for a transmitting loop for 40M that will require no tuning over the band.

Hi Tom,

A couple of observations re: doodle #6. Yes, placing the coupler at the loop feed-point is an ideal way to feed the loop all bands using 50 ohm coax. I assume you refer to the SGC-235 ... their 500W auto coupler. I agree with your statement of isolating the coupler from ground. More accurately, you are attempting to 'block off' or 'choke' RF from travelling on the outside of the shield of the coax. to ground. This can be accomplished by using an isolation transformer as you show in your illustration. This technique is a bit complicated (mechanically) as it will sit between the coax terminal on the coupler and the end of the coax. I also observe you are using an impedance transformation which is not necessary; the input impedance of the coupler is designed for 50 ohms .... the impedance of the coax feed line ... therefore if you are designing an isolation transformer it must be 1:1. The most convenient way to achieve this goal would be to provide an RF choke at this point. Simply place ferrite beads on the coax at the point it meets the coupler .... there are commercial versions available ... or simply coil 20 ft or so of the coax where it meets the coupler.

I notice that SGC does not specify the output impedance range of their 500 watt model. The reason I suspect is that the range is limited by virtue of the power. What I mean is that any coupler they manufacture may have the capability of matching a very broad range as long as the power being fed is QRP or at least low ... say 20 watts. However as you increase the power the range constricts ... and often severely. It is just that under a particular set of conditions the coupler may work just fine and present a reasonable SWR. However as you increase the power, the stress of higher voltages or currents my go beyond the capabilities of some components.

My suggestions: get rid of the complicating transformer, and use a RF choke. Be very cautious as you approach the 500w output level ... take it slow .... I doubt very much that the coupler will safely handle 500 watts on all frequencies on all bands.

5516. Ferrite Rod Antenna (Tuned) with old Radio parts?

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-18 22:02:59 UTC
From: Matt B.
Topic: 5516 Message: 5516

I want to build a ferrite rod antenna similar to CCrane's Twin Coil Ferrite. I want it for my home stereo and do not want to have a wire loop antenna sitting on my small end table.

For $3 I just bought an old Sony transistor portable AM only radio: TR 84 "Super Sensitivity" circa. 1960 . It has a 6" rod with a 3 Gang variable cap. It is a Super HET radio.

I would like to know if I can remove the whole antenna and tuner and any amplifier/mixer/filtering system it has.
I would put the rod into a plastic tube or box and put the electronics into another box with a tuning knob on it.

You can separate the LF Amp and the Receiver by removing a steel link between two screws. I don't understand what this means but it sounds related to what I want to do.
There are 3 screws in a row labeled; GROUND, IN, OUT.
The link links together the IN and OUT screws. When you remove it, you cannot turn the radio ON and there is no volume or sound at all.

Please help if you can. I cannot afford a commercial form of this antenna. I do have good experience with working with electronic parts and wiring so I can do it myself with your advice on how to separate the circuits I need.

(snip)

What about hiding a loop around the back of a picture frame
or around the back of the end table or around the back of
the couch? Any of those will interact with a lot more wave
energy than a ferrite rod will. Just sayin'.

Ooooh! I never thought of doing that. That would be an interesting way of hiding a loop indoors. Now, if I just had one of those large Studebaker emblems I could have the best of both worlds. :{)

There is pretty much zero space for a wire loop and if I hid it somewhere I would have no way to turn it for reception.

If I could rig up a loop in the attic on a rotor...but then how would I tune the tuning cap?...

True, you might have to make two, oriented at about 90
degrees with respect to each other with a switch to pick the
one best oriented.

> If I could rig up a loop in the attic on a rotor...but then how would I
> tune the tuning cap?...

You can put the tuning cap at the radio with a reduction in
the Q, since the wire losses between the capacitor and loop
are included in the resonant losses. Of you use one of
Chris Trask's neat DC tuned remote varactor variable
capacitors to let you put the capacitors at a remote
location and tune then with a pot across a DC supply to
produce a variable DC tuning voltage.

From: roodyjs
Topic: 5522 Message: 5522

I have just recently become interested in the possibilities of constructing a loop antenna at my QTH. I have a small yard that is about 20 ft by 20 ft. My thoughts are to use the 6' high fence to support a full wave 20meter loop (horizontal). I can also try a roof-mounted version. Roof is about 25 ft high.

I am currently using a Par Electronics SWL sloper for receiving and a Tarheel mobile screwdriver, ground mounted with 50 radials for transmitting. Max power is under 100 watts.

My questions have to do with what I can expect to see in receive or transmit improvements with a loop.

As I am pretty new to understanding the qualities and design of such an antenna, I hope that some of you more experienced folks can offer some helpful insight and advice.

Regards,

Jim KC3SN

Date: 2008-08-22 07:37:41 UTC
From: Mike
Topic: 5525 Message: 5525

Dear HF group members

UKQRM now has 371 members and 1601 shortwave radio users have signed the e-petition calling for a end to power line Ethernet here in the UK
http://petitions.number10.gov.uk/SaveShortwave/

A number of our members suffering this appalling interference have had the matter resolved by Ofcom and BT (myself included)
When a complaint is made BT has behaved well and removed the adaptors from the offending property!

However the fight is not over yet! Only last night another set came on line and I now have the interference again only this time from a property 500 or more yards from me!
Also its quite clear that the signal from these horrid devices is propagating in the evenings as this morning its much weaker!

I also found it was leaking into the mains supply and telephone lines locally!

You can make a difference and safeguard your hobby, pastime or professional use of HF by signing the petition (UK residents, those with UK voting rights only)
And or joining UKQRM to lend support.

http://tech.groups.yahoo.com/group/UKQRM/

We need those who are passionate about radio, with legal understanding, technical abilities those that just care.

If a stand is not made now, then shortwave will become swampt with these devices.
Already many suppliers are listing them cheaply.

Thanks

Mike UKQRM

http://www.mikeandsniffy.co.uk/UKQRM/

The end of world broadcasting?

Cheers Mike

Lovely. Some questions:

Since you are using an isolation balun to couple to the
transmission line, why do you need an additional loop to act
as pickup? Why not just tie the balun across 1 turn of the
tuned coil?

How did you arrive at a 9:1 ratio for the balun?

What is the balun core material?

If you are up for experimental variations, you might see a better selectivity (Q) signal strength combination if you eliminate the extra coupling turn (and the stray capacitance it adds to your tuning), and just pass one end of the main coil through the core as the coupling winding.

If the secondary also has 1 turn, this puts 50 ohms in series with the tuned loop. If the 50 ohm line is coupled with 2 turns, it puts 50/4=12.5 ohms in series with the loop, raising its Q up less than 4 times (which pumps up the signal) but lowering the output signal by half. The ideal balance between increasing the signal with a higher Q and lowering it with output turns depends on the signal bandwidth you require and how high a Q the loop has without the coupling transformer loading it. I suspect the optimum load is that which lowers the loop Q by about half. But only a few turns on the secondary should be close.

Just a thought.

Thanks for the replies gentlemen.

I have received a schematic for a pre-amp for a ferrite system and I will give it a try.

I would really like to get a hold of one of Stormwise's 10" ferrite rods or even a 8" rod from an old radio like a Grundig.
It seems that Stormwise cannot ship the ferrite rods to Canada as the website seems to imply this.

You can approximate large rods by stacking long form ferrite
beads. For below 2MHz, I like the Steward LFB beads,
available in Canada from Digikey.

An example is part number LFB159079-000 at just over USD 1,
each. 16mm diameter, 28.6mm long with 8mm hole. These
stack up nicely in thin walled PVC pipe.

Thanks John, that looks like a good idea. I'll plug in the numbers and see about wiring up a rod made from those beads.

I forgot to mention that when you make a rod in segments,
this way, you have an additional degree of freedom you don't
have with a solid rod. You can trade off loss against
permeability by adding non conductive shims (i.e. layers of
paper) between the beads. I few years ago, I did some
experiments that explored this variable and found that some
specific shim thickness per bead gave the highest overall Q
at any given frequency. So the rod can be tuned to perform
best at your choice of frequency. The distribution of these
shims along the rod also had a distinct effect, with gaps
near the center having a larger effect than those near the
ends. Just something else to play with.

I remember when John did these experiments, and it's a wonderful method
for reducing the eddy current losses in the ferrite material.

I think that my paper on a remotely tuned ferrite rod antenna is still
in the group files section. If not, you can find it on my webpage at:

http://tinyurl.com/ys293g

If you remove the tuning components, you'll end up with a good quality
wideband active ferrite rod antenna.

I'm spending my time these days on yet another remotely tuned loop
antenna, and this one is much simplier and far quieter than the one I
published in QEX years ago. I'll have that done for the loop antenna groupd
later this week.

Chris, you've obviously spent a lot of time working with ferrite core
loops. How does a ferrite core loop compare in performance to an air
core loop?

I know ferrite works well for VLF and MW, but how about SW?

The performance of the active ferrite rod antenna that I made for that paper is comparable to the performance of the active 1m diameter air-cored loop that I have been using for many years, and both antennas tune over about the same range. I haven't made any qualitative measurements between the two, and I suppose that I should do so as it is an aspect of some interest.

In the meantime, I'm about to finish up some work on a new form of remotely-tuned air-cored loop that does not have an amplifier. Instead, it has an impedance matching network that couples the loop antenna to 50-ohm coaxial cable through a series of wideband transformers. It uses a balanced form of tuning that seems to do away with the usual harmonic interference from nearby AM BCB stations. The S/N performance is much better than that of either of the active loops. When I get this work done along I should perhaps set up a small antenna range and compare all three in terms of signal gain and S/N ratio. However, I would also like to build a remotely-tuned shielded loop and add that to the comparison as that form of receiving antenna is also of interest.

Thanks, Chris. I need a small, quick to set up and take down antenna
for AM/MW and SW up to 10m. Last night I was experimenting with a 1m
loop tuned with a 385 pf tuning cap, with a coax pickup loop going to
an Icom R75. I was getting good signals from 60 m - 20 m, and it was

easy to unplug the loop, plug in my outdoor 80 dipole, back and forth.

Though the S reading was a tad lower for the loop, it picked up everything the dipole picked up, and the low sig to noise ratio made it all equally listenable.

I think some of my questions are answered on ferrite vs loop in the BBC Whitepaper I just uploaded to the Files section.

5544. "Accidental" loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-27 14:26:44 UTC
From: Misha
Topic: 5544 Message: 5544

Hello everybody!
My home environment is very noisy, this is why I joined this group, to read about lower noise antennas.

I have a short (3ft) cable plugged into my FT-817, terminated with alligator clips so I can hook it up to different antennas quickly when experimenting. I noticed that when I clip the center conductor wire to the ground lug on the back of the transceiver, I can still hear enough signal without any of the noise! The cable shield is not connected to anything on the far end and is providing the electrical shielding (not perfect), while the center conductor forms a magnetic loop.
This "antenna" definitely works better than a straight wire, and S/N is great for broadcast signals and stronger ham signals. It works from 530kHz all the way to UHF (where it isn't a magnetic loop anymore). Of course, I can't transmit, because the efficiency and SWR would be horrible.

5545. Varactor-Tuned Loop Antennas

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-27 19:30:52 UTC
From: Chris Trask
Topic: 5545 Message: 5545

I finally completed the work that I have been doing on a simple varactor-tuned loop antenna with interchangeable antenna elements. The documentation is available at:

http://tinyurl.com/6lht4y

A little more work needs to be done here as the inductance of the transformers is limiting the high end of the tuning range. However, the results obtained at this point show that the sensitivity is far better than I had anticipated, and together with the very good S/N performance this design rivals the performance my earlier active loop antenna that was published in QEX back in 2003.

Corrections and constructive comments are always appreciated.

David; Thanks for the videos. I can hear you switching N-S vs E-W but am wondering what kind of gain you are getting w/ that large of a loop? What is your location (urban/suburban/rural)? What kind of receiver? I made a 3.5 ft (effective) diameter BCB loop and compared to a 2 ft BCB loop I hear little benefit in the larger loop. This due I suppose to high RF and QRM around here.

Tnx,

Mark

Hello.folks!
To my great surprise, I happened to see the
http://www.makela.info/lyhytaaltokuuntelu/index.p...
This man, Raimo Makela, who has written a Guide for DX-listeners, called Antenneilla Aalloille (With Antennas to the Waves), shows, how to make a simple closed-triangle-shaped directive antenna, that attenuates signals from one direction, while amplifies the signals coming from the opposite direction.
This Mini-Directive-Loop-Antenna, which was made much according to the K9AY, is only 1,5 meter high and 1,0 meter broad. A great gift for them, who have very little room inside/outside!
I made my own prototype, to see, if it really works as promised, and I was really very positively surprised! It is really very directive to one direction, while attenuating signals from the opposite direction!
This is, what I have been thinking of for a long time! A dream come true, as you Anglo-Saxon-Americans so nicely say!
What I made, is staying in my listening-room as a raw model only, so far, but I have plans to make a little larger one to use with my new-bought rotator, to see, if I can finally receive some DX in Spain.
I am going to connect it with some of my many Antenna Amplifiers and Preselectors etc. one after another, to see, if it really can be the winner of my other many receiving media...

Any advice and positive ideas will be received with gratitude.

You can sometimes just put a little AM radio next to a big older radio and use the big radio to boost the signal of the little radio. It might be the big radio is a broken tube radio and the little radio is a digital thing with a smaller loop. There is a youtube video showing this. So I am sure you can take the LOOP and TANK circuit out of a radio and use it boost other radios.

5555. Slightly off topic MW reception question

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-28 13:01:49 UTC
From: Doug Kniffen
Topic: 5555 Message: 5555

Does anyone know what causes MW reception strength to vary significantly (10+ S units) and rapidly (~1.5 Hertz)? It sounds just like somebody is rapidly cranking the volume control up and down.

Years ago I heard this on BBC shortwave broadcasts. It was so hard to listen through audio rapidly changing from crystal clear to mostly static that I gave up.

Now it's been happening on MW in the last month. Doesn't matter what radio I use (3), or what antenna I try (big outdoor wire, small untuned loop, or built in ferrite). The problem seems to bounce around the MW band. If you hear it on one station, and change frequency to a clear station, you can often go back to the original station when the problem shows up at the second station. With no more than several minutes clear reception at any frequency, re-tuning really isn't a solution.

The problem seems to be some natural phenomena, but if nobody else has it it must be caused by some sort of local interference. If it is natural; What is the cause, and is there a particular antenna design that will minimize the problem?

Thanks,
Doug Kniffen

Hi Doug,

What you describe is the result of evening sky wave propagation. Generally speaking all MW reception during the daylight hours is direct and more or less line of sight (there is some bending). If you do DX listening during the day on MW then your setup has to deal with low signal levels and local noise. These daytime DX stations are in the 100 to 300 mile range. At night it becomes completely different and stations come in from thousands of miles away with S9 signals.

The difference is due to the interaction between the ionosphere and MW signals. During the day the Ionospheric conditions are such that MW signals are not reflected (the cause of propagation over long distances) and the layers change at night such that these conditions will propagate MW signals over long distances (reflections). When listening to a particular station on a particular frequency it is usually steady for a period of time and then fades out .... often to be replaced by a different station at a different location. How rapidly this happens depends on natural phenomena such as magnetic field fluctuations, cosmic ray showers, etc.

As your location moves closer to the north or south pole magnetic fluctuations become more rapid and intense and radio reception may take on a rapid flutter (Arctic flutter). So to answer your direct questions what you experience is a result of the changing characteristics of the ionosphere which in turn is created and modified by the interaction of the cosmic rays from the sun interacting with the earth's magnetic field. It is not local inference and there is not much you can do about it re: antenna design.

Jim

MW signals propagate in two ways. The first is by what is termed ground wave. This is very straightforward -- signal leaves transmitter tower and travels along near the ground until there's not enough left of the wave to be received. (In reality it's not quite that simple, but it's close enough for this discussion.) When the sun is high in the sky, ground wave is the primary method of MW propagation.

The second method is sky wave. The signal travels up into the sky, bounces off one of the layers of the atmosphere, and is reflected back toward earth. Sky wave propagation is not a big factor during most of the day time. At night, however, it becomes a huge factor and is the reason you can fairly easily hear stations many hundreds of miles away.

Ground wave is still in play at night, but doesn't propagate in that way any further than it does during the day. You get local signals mostly via ground wave and distant signals mostly via sky wave. The ability of the ionosphere to reflect MW signals is affected by a number of things, most of them related to solar activity of one kind or another. As the ionosphere changes, propagation of the signals bouncing off that layer change, sometimes profoundly, as you've noticed.

It's not at all uncommon to get a crystal clear signal from a very distant station. It sounds as though it's located right down the block. Then, quite suddenly, it's gone, sometimes replaced by another station that's just as clear as the first was, sometimes by static. It's just the nature of long distance MW listening. A longer, larger antenna can help in some circumstances, but if the ionosphere changes so that a different signal is dominant at your location, there's really nothing you can do about it.

I meant to add this in my last reply.

You didn't mention what radio(s) you're using. If you have Sync AM available, you might try using that. It should help if carrier fading is causing the pulsing.

If your radio has different settings for AGC, you can try playing with that. Assuming the radio allows it, sometimes turning AGC off completely and controlling the RF gain by hand can smooth things out.

Using LSB/USB can also sometimes help with brief fading.

When the station fades away for long periods, that's probably due to the ionosphere and there's nothing you can do about it.

David; Wondering what BCB is like on a typical night in Scotland. Do you consistently have skip from USA & other parts of the world? Or are some nights a mush of undefinable signals? If I want to hear stations to the west of me, killing stations to the east - I am more or less in the middle of the continent in Wisconsin - I have to listen close to dawn. Fun coincidence: We have a local 50KW here in Milwaukee. I nulled it using the internal ferrite on the KA2100 portable radio two nights ago when skip was good & noise was down and got a positive ID on WBBR. Next day I see your WBBR video on YouTube. Using radio-locator.com I see they are 50KW beaming east toward you. Man, they get out. Question: Watt for watt & on average, do you notice the directional USA AMs beaming east are stronger than the omni's?

Now that I have better gear and winter approaches, I am looking forward to real DX on BCB. Until now I've only heard hets on BCB. Now I'm going for the "channels between the channels".

Fun stuff.

hi i am not getting the big peaks to usa etc untill 05.30 in the morning local time here. its a bit early in the season to be getting them at night yet but in saying that i am not up all night i am usually up around 04.00 and sometimes they are just starting or i have to wait half hour or so for them to come in. i dont get them every time for example this morning WEGP on 1390 was extremely weak in and out of noise but was very strong on wednesday morning its all down to propagation. the reason i built the loops i have no room for antennas in the garden and all i am interested in is usa carribean etc and africa thats why i put them east west and north south so anything east is a bonus and there is nothing much to the north of me and i wanted as much gain and nulling as i could get in favour of those directions. and after reading many articles etc it seemed bigger loops had more gain but i could be wrong i really dont know what gain the two big loops have. yes i think the directional ones are much stronger than the omni"s. i have set myself a challenge there is one or two stations coming in along with or just under WTIC on 1080 and i am trying to id them also there is a nigerian pirate on 917 khz also after that one. many thanks for your time david .... scotland uk

Done. There should be an email announcement to the group shortly. I revised the paper this morning to correct a number of spelling and grammar errors, as well as move a couple of illustrations so that they flowed better with the text.

Subject: [loopantennas] Mini-Directive- One-Point of the Compass-Loop

Hello.folks!
To my great surprise, I happened to see the http://www.makela. info/lyhytaaltok uuntelu/index. p...
This man, Raimo Makela, who has written a Guide for DX-listeners, called Antenneilla Aalloille (With Antennas to the Waves), shows, how to make a simple closed-triangle-shaped directive antenna, that attenuates signals from one direction, while amplifies the signals coming from the opposite direction.
This Mini-Directive- Loop-Antenna, which was made much according to the K9AY, is only 1,5 meter high and 1,0 meter broad. A great gift for them, who have very little room inside/outside!
I made my own prototype, to see, if it really works as promised, and I was really very positively surprised! It is really very directive to one direction, while attenuating signals from the opposite direction!

This is, what I have been thinking of for a long time! A dream come true, as you Anglo-Saxon- Americans so nicely say!
What I made, is staying in my listening-room as a raw model only, so far, but I have plans to make a little larger one to use with my new-bought rotator, to see, if I can finally receive some DX in Spain.
I am going to connect it with some of my many Antenna Amplifiers and Preselectors etc. one after another, to see, if it really can be the winner of my other many receiving media...

Any advice and positive ideas will be received with gratitude.

terve,

Kiitoksia terveisistä. Kun kaksi K9AY antennia on yhdessä, voidaan tosiaan valita toinen ja sitten toinen.

Olet oikeassa, yksi mini K9AY-antenni voidaan laittaa kiinni roottoriin. Tosin näin pienen antennin vastaanottoteho ei ole mitenkään suuri, ja siksi DX-spesialistit ovat hankkineet tehdastekoisia wellbrookin aktiiviantenneja. EWE-antenni toimii pienelläkin pihalla.

Hyviä kokeiluja!

I took the original address, removed the trailing characters after the 'p', then added 'hp' to the end ('http://www.makela.info/lyhytaaltokuuntelu/index.php'). That brought up the page as intended.

Unfortunately, my Finnish is a bit rusty. I clicked the Antennit link and from your original message the "Antenneilla aalloille" link. Sadly, I came upon only more Finnish. With the romance languages I can sometimes hack my way through it, but I'm afraid Finnish is not something I'm likely to understand at any point in this lifetime.

Perhaps you could provide us with a rough translation. A mini-K9AY does sound interesting.

Chris;

Antenna shootouts - great idea. I will be posting shortly a series of tests I recorded (yes, audio files will be posted) comparing two receivers barefoot (Sat 800 & RP 2100) to a 2ft 15 turn loop vs the CCrane Twin-Ferrite. The tests will also show the results of the T-F/Loop combo - the combo being winner in the tests for s/n and nulling.

-Mark

> The performance of the active ferrite rod antenna that I made for that paper is comparable to the performance of the active 1m diameter air-cored loop that I have been using for many years, and both antennas tune over about the same range. I haven't made any qualitative measurements between the two, and I suppose that I should do so as it is an aspect of some interest.

> When I get this work done along I should perhaps set up a small antenna range and compare all three in terms of signal gain and S/N ratio.

Thank you both, Jay Heyl and Larry Wild!
Please see the exact email address, given to me by Raimo Makela himself.
It wil direct you to the right page of the Mini-K9AY.
Sorry for the mess?
I just happened to give wrong addresses twice or more.
Please, see down. There are two equal addresses, the right ones, at last!
You will see the drawings and the measures in meters.
The other things are probably not as important, if you want to build the antenna?
R=resistor
m=meter
vaimentaa=attenuate
suunnasta=from direction
antennivahvistin=antenna amplifier
jne=etc.

Best Regards from Amigo

Sorry, but for some unknown reason, I am not able to wipe out the extra words down here!
At least the right addresses are ther twice!
Ami

Please, try the following email address down here to find detail of the Mini-K9AY.directive Antenna.

5574. Resonating transmitting loop at feed point?

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-28 22:13:54 UTC
From: lbradenjr
Topic: 5574 Message: 5574

Hello,

I'm new to the group with a question concerning one turn transmitting magnetic loop. Has there been information published about the voltage distribution over the wide range of frequencies that a typical loop, given enough capacitance, can be tuned to resonance? Why is the high voltage capacitor typically positioned on the side opposite the feed point?

73,

Larry Braden

> rapidly cranking the volume control up and down.

Either of two possibilities are:

1. If the rate is extremely regular, it could be a "beat frequency" between stations on the same frequency, but not exactly the same. A 1.5 Hz difference between them would cause a 1.5 Hz variation in combined signal strength. Not likely that this is what you're hearing, but it might be.

2. More likely, it is the changing ionosphere, and multiple paths and path lengths (delays) that change between in- and out-of-phase with one another. It is a known phenomenon for nearly 100 years. Sometimes the fluctuations are slow, sometimes they are rapid.

Andy

Sent: Friday, August 29, 2008 11:29:51 AM
Subject: Re: [K9AYloop] Mini-K9AY

"Mini-K9AY

K9AY antenna has triangular shape, height being 7.62 metres and width about 9.3 metres. Mini version of the antenna is much smaller. Height is 1.5 metres and width only 1 metre.

To function effectively Mini-K9AY antenna requires terminal resistor (marked as "R" in the picture, with value of 125 - 200 Ohms). The impedance of the antenna is approximately 200 Ohms. The antenna must be connected with 4:1-impedance transformer to 50 Ohm coaxial cable and the receiver.

Mini-K9AY antenna works best on medium wave on lower frequencies of shortwave (2.3 - 5.1 MHz). It is fairly effective also on other shortwave frequencies.

Mini-K9AY antenna is very suitable for noisy environment: it attenuates nearby noise. The antenna gets it directional properties with its terminating resistor, and adjusting it may be useful to find the least noisy reception. The antenna receives best from the direction of the terminating resistor ("R" in the picture).

Amplification of the Mini-K9AY is on medium wave abound -60 dB, and on low parts of SW-35 dB at best. The angle of the receiving beam is ±90°. The arrival angle is 25-30°. The attenuation of the incoming signal from backlobe depends on the value of the terminating resistor and may be 15-25 dB.

Since Mini-K9AY has weaker gain than its big brother (on MW about 30 dB and in tropicla bans about 10 dB less), I recommend using a good-quality, low-noise preamplifier. "

5580. Re:Slightly off topic MW reception question

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-08-29 12:38:45 UTC
From: gmcjetpilot@yahoo.com
Topic: 5555 Message: 5580

Clearly it is the reception fairies the fly around. Some time they get drunk and mess around with our radios....ha ha......yes it can be anything from propagation to local or atmo interferance from may sources.

The "wave" or swoosh where the volumn goes from good and strong to soft/faint and back again to strong sounds like skip or skywave propagation. (marginal skip). You should not hear this with local stations which are more line of sight or ground wave. On shortwave I can get New zealand (east coast US about 8000 miles) late at night on SW; some times it comes in strong, but than towards the end of their broadcast slot, I'll get time of day (night) fade, which sounds like what you are talking about.

COULD BE?

One time I had this FADE deal and it turned out to be my antenna coaxial, which was failing. Just a small movement of the coaxial made the internal contact so marginal, it made this fade affect happen. It was weird and affected local MW stations. I figured it out. The coaxial was bought at a ham fest and looked top quality. It was crud. I bought my own coax and connectors and made my own patch cables. They work well.

The single capacitor is used that way so as to keep the loop balanced. You can accomplish the same thing with a pair of capacitors at the feedpoint, one at each end of the loop.

73,
Larry Braden
KB3PCU

The tuning capacitor end of a one-turn transmitting loop is the
high-impedance end of the loop that develops the highest voltage. The midpoint of the
loop opposite the tuning capacitor is the low impedance and low voltage side of
the loop and can be considered the center-tap point of the loop. Since most
hams use low impedance 50 ohm coax cable as a transmission line it is common
practice to feed the loop at the low impedance center-tap end for best match.
It is most common to use a smaller 50 ohm coupling loop at the low impedance
end or else a gamma match.

Also there is a voltage null at the exact midpoint center-tap of the loop
opposite the tuning capacitor so that point can be grounded without affecting
the operation of the loop and it can be connected to the coax shield ground.

Subject: Re: [K9AYloop] Mini-K9AY

"Mini-K9AY

K9AY antenna has triangular shape, height being 7.62 metres and width about 9.3 metres. Mini version of the antenna is much smaller. Height is 1.5 metres and width only 1 metre.

To function effectively Mini-K9AY antenna requires terminal resistor (marked as "R" in the picture, with value of 125 - 200 Ohms). The impedance of the antenna is approximately 200 Ohms. The antenna must be connected with 4:1-impedance transformer to 50 Ohm coaxial cable and the receiver.

Mini-K9AY antenna works best on medium wave on lower frequencies of shortwave (2.3 - 5.1 MHz). It is fairly effective also on other shortwave frequencies.

Mini-K9AY antenna is very suitable for noisy environment: it attenuates nearby noise. The antenna gets it directional properties with its terminating resistor, and adjusting it may be useful to find the least noisy reception. The antenna receives best from the direction of the terminating resistor ("R" in the picture).

Amplification of the Mini-K9AY is on medium wave abound -60 dB, and on low parts of SW-35 dB at best. The angle of the receiving beam is ±90°. The arrival angle is 25-30°. The attenuation of the incoming signal from backlobe depends on the value of the terminating resistor and may be 15-25 dB.

Since Mini-K9AY has weaker gain than its big brother (on MW about 30 dB and in tropicla bans about 10 dB less), I recommend using a good-quality, low-noise preamplifier. "

73, Mauno

Hi again!
Would you kindly tell us all about your experiences
when building and testing this "miracle"?

I am sure, that if done with skill, this type of antenna,
equipped with a proper amplifier and rotator,
can be a very effective and rather cheap "fishing" media.

Awaiting for your positive comments and experiences,
73 de Ami

A few people asked about where to obtain some of the parts for this, such as the varactors and transformer cores. Best place I could think of was Dan's Small Parts:

<http://www.danssmallpartsandkits.net>

With a couple of minor substitutions, he has the varactors, cores, and magnet wire. The remaining parts are fairly common. He also has a pair of reduction drives which can be used on the tuning control if desired. I put all of this on a new page at the end of the document.

I would be interested in hearing from others overseas about part sources so that they can be added to the list. I'm also trying to find someone who would make parts kits available, but haven't heard anything back as of yet.

Chris

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.
http://members.cts.com/king/j/jlkolb/site/dif_fet.pdf

Justice AM Antenna With Twin Coil Ferrite

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

* Select-A-Tenna Model #541M (Passive)
- - - http://www.selectatenna.com/

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.
http://ecforster.netfirms.com/LpAnt/Doc1.html

Very Low Frequency (VLF) Up-Converter
STORMWISE: Palomar VLF Converter allows you to use your ordinary ShortWave Radio to listen below the AM Broadcast Band. Directly Tune VLF Stations of 10 KHz to 500 KHz using your existing ShortWave Radio. The VLF Converter easily connects between the Antenna and the Radio.

5596. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-09-01 19:59:07 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 5596

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

So I've heard since then. The web page that showed that schematic with
the two current feedback amplifiers wasn't entirely clear.

My first impression was that it was a balanced form of a halo antenna.
Every bit as cool as a circular folded dipole.

From: trident_3b
Topic: 5605 Message: 5605

Hi,

I've bought a replacement unipolar stepper motor for my AEA Isoloop
and it has 6 wires (White, Yellow, Orange, Grey, Black and Brown). The
LC-2 controller has 4 (White, Green, Red and Black).
I believe a unipolar motor can also be employed as a bipolar motor.
Can anyone tell me how they match up...?!

MTIA,
Andrew

> Can anyone tell me how they match up...?!

I would be absolutely amazed if there was a world wide color code standard for step motor lead wires. But 6 and 8 lead unipolar, 4 phase motors can certainly be used with bipolar drivers. It is the 5 lead motors that cannot easily be driven as bipolars.

To make the motor step, both of its two phases must be magnetizable in each of two directions (and possibly not magnetized at all). Bipolar drivers can do this with only one winding per phase, since they can drive that winding in either direction. But unipolar drive requires two coils (one wound each way), so that you can use one or the other with similar drive to produce both magnetization polarities. The effective center tap of this pair of windings connected in series is the common connection for the two unipolar drive current paths.

If you just disconnect that center tap, and drive the series pair of windings with a bipolar driver, you get the two magnetization directions. Since those drive amperes are passing through twice as many turns as when the unipolar winding uses only one half at a time, it takes only half the unipolar drive current to get the same torque with bipolar drive. But it also takes twice the applied voltage to get that torque (at the half current) at the same speed, because the two windings in series have 4 times the inductance and the back EMF of the windings is a per turn effect, so twice the turns generates twice the back EMF.

There are also some 8 lead steppers that are universal replacement types, that can have their 2 phases of half windings connected in series for unipolar or high voltage, low current bipolar use, or connected in parallel for bipolar, low voltage, high current use. I have also pulled the ends of some 6 lead unipolar motors and separated one of the half windings from the center tap lead and attached the other to a new lead, making an 8 lead motor out of it.

In your case, you find the two pairs of leads that produce
the higher resistance readings to act as the ends of bipolar
driven windings. Just tape up the other two leads (the
winding center taps).

--
Regards,

John Popelish

I can view video just fine with the provided link.
Might try a virus scan.

5614. Single turn vs Double Turns

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-09-04 06:10:26 UTC
From: oh6bi
Topic: 5614 Message: 5614

Hello all.

I built the rockloop based on dl1gsj article.
(http://www.qsl.net/dl1gsj/html/rockloop.html)
Thanks Joachim.

The condensator i used is butterfly 2x40 pF, toroid is made by Philips, I dont know the specs. I used it like in series - 3 to 20pF, and I was able to run even 100 Watts , no sparking in cap and no heating in the toroid. First test was sidelengths abt 80 cm, loop was working nicely from 18 MHz to 29 MHz. I made some local QSOs at 10m with good reports.

But my favourite band is 14 MHz, so I put some more wire to the loop sides abt 90 cm and got the resonance at 20m. Same time I loost 28 MHz.

I made some calculations: with the same length of loop wire I could make two turns and reach lower resonance freq. to reach lower band with same material. Goeing to test it in the evening.

My question is : what happens to system when using two turns, shall the efficiency drop down compared to one turn loop ?

73s de rami, oh6bi

Yes, the efficiency will decrease as the number of turns increases. For 20M, you can use a 64cm diameter loop and get good efficiency. The larger the diameter of the conductor, the better the efficiency.

5616. Rock Loop agn

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-09-05 06:58:27 UTC
From: oh6bi
Topic: 5616 Message: 5616

Hi All !

After several messages and replies in Yahoo Groups:
CW-QRP (ex codewarriors), hfpack, loopantennas and MQFD

I apreciate good replies and information what I got from all of you
guys !!

I decided to make this message for all because different
replies in different groups, so that everyone can see the result.

In very first messge in hfpack I asked info abt magloops.
After that I decided to make RockLoop:

I built the rockloop based on dl1gsj article.
(http://www.qsl.net/dl1gsj/html/rockloop.html)
Thanks Joachim.

The condensator I used is butterfly 2x40 pF, toroid is made by
Philips, I dont know the specs. I used capacitor like in series - 3
to 20pF, and I was able to run even 100 Watts , no sparking in cap
and no heating in the toroid. The loop side has 5 turns and coax side
has 20 turns. Tested other number of turns both sides and this gave
best swr with philips.
Loop Wire is 1.5 sqmm tinned copper and the coax side wire is .5 sqmm
copper, both standard insulated electric installation wires.

First test was sidelengths abt 80 cm, loop was working nicely
from 18 MHz to 29 MHz. I made some local QSOs at
10m with good reports. But my favourite band is 14 MHz,
so I put some more wire to the loopsides abt 90 cm and got the
resonance at 20m. Same time I lost 28 MHz.

Problem is the capacitor, needed bigger one,
Because nowdays it is difficult to find good variables from here
I tried to solve 14 MHz this time by giving more inductance to
get resonance frequency lower using same components.
I used some programs to find out how much does the inductance grow
when making two turns from same flexible loop radiator.
I got inductance more than double of the original loop and
resonance will go even lower than needed 14 MHz.
I already knew some things with big loops near the wavelength,
radiation resictance and the area of loop are important.

OK , it is clear that making double ring that reduses the loop area
will drop the efficiency, but I didnt know how much. Anyway that loop
size I am using is not so good with 14 MHz compared to 28 MHz, just

to get it working there. In this case loss resistance stays same ,
frequency and area are different. Q will also change.

Some programs are giving efficiency for 1 m diameter loop :
28 MHz 85 percent eff. and 14 MHz 33 percent eff. .

I made double turn question to find info and opinnions from the
groups.

After that I found from aa5tb web site good information.
These formulas, copied from http://www.aa5tb.com/loop.html
are giving good mathematical answers:

Radiation Resistance, Ohms: RR = (3.38×10↑-8)(f²A)²
Loss Resistance, Ohms: RL = (9.96×10↑-4)(√f)(S/d)
Efficiency: η; = RR/(RR+RL)
Inductance, Henrys: L = (1.9×10↑-8)S[7.353log10(96S/πd)-
6.386]
Inductive Reactance, Ohms: XL = 2πf(L×10□3;6)
Tuning Capacitor, Farads: CT = 1/2πf(L×↑6)
Quality Factor: Q = (f×10↑6)/Δf = XL/2(RR + RL)
Bandwidth, Hertz: [6;f = (f×10↑6)/Q = [(f1-f2)×10↑6]
Distributed Capacity: pF: CD = 0.82S
Capacitor Potential, Volts: VC = √(PXLQ)
Capacitor Voltage Rating: 75,000V/in

where
f = operating frequency, MHz
A = area of loop, square feet
S = conductor length, feet
d = conductor diameter, inches
η = decimal value; dB = 10 log10η
P = transmitter power, Watts

It was tricky thing to make turns double.. you can try it with
piece of rope. In normal position the capacitor is at the top of the
loop and toroid is down. Making two turns moves toroid to the top
with capacitor.
So, I made triple turns and got toroid to correct place down.
I made new loopwire with original 80 cm sidelengths and
before changing turns I made measurings and got resonances at
28, 24, 21 and 18 MHz . Three turns model was resonating from
11,7 to 16.5 MHz. At 14 MHz resonance was good and strong.
But Loop diameter came quite small, so I didnt try to make QSOs.

At Alexandres web site you can see good way to solve capacitor
problem:
http://hps.infolink.com.br/py1ahd/gallery19.htm

Also Joachim suggested extra capacitors. Now I have to go local shop
to find good capasitors for lower bands.
Values I vill test are 10 pF, 20pF, 30pF and 40pF.
I am not sure if this local shop has silver micas but at least
they have polystyrene models.

Best regards and 73s de rami, oh6bi

To know is either to ask or, even better, to try and test oneself...
Only time will be lost, but often good results received.
That is one of the secrets to gain more self-confidence and self-esteem.

By the way, did you notice the Loop called Mini-K9AY?

It is a loop, which attenuates one direction while amplifies
the opposite direction. The figure 8 is no more there, only the other half!
Amplification varies between -60 dB on MW to -35 dB on the lower SW.
Attenuation from the opposite direction may be between 15-25 dB!

Just what I have been thinking and hoping for years!

The smallest version is only 1,5 meters high and 1,0 meter broad.
It is turnable and when used with a rotator, it can be on the roof
or yard. In the attic it will work very well also.

I thought, that a bigger version (2,5 x 2,0 m) might give a little stronger signal,
but a better idea here may be to continue to use the Wellbrook ALA 100M
(serial number 0009) all-band-amplifier to boost the incoming signal,
because it is a very quiet one. I was really surprised to notice this, because
I did not know, that the 100M would like to be used with so short a wire,
3,69 metres!
The longer version would demand only twice that, 7,38 meters...

This "Mini-Master" uses a resistor on one of the lower sides and
a small Toroid or iron powder ring on the other. It works well with
a coaxial cable and therefor an A.T.U. is not necessary, but I want to use one,
because it amplifies a little more the signals here.

Thanks for your videos, David and good luck for your efforts in your hobby!

Ami

Matching the antenna to the load and using narrow-band tuning can make a great deal of difference in the S/N ratio. I did just that for an HF loop recently:

My first impression was that it was a balanced form of a halo antenna.
Every bit as cool as a circular folded dipole.

Chris

dear chris

my understanding is that these do not offer much gain, the halo or its folded dipole
version

best

Loops are usually among the best at rejecting locally generated noise,
but they are no immune. If you have a lot of RF noise in your area,
the antenna is going to pick some of it up.

Depending on the power and antenna pattern of the station in question,
you may also be asking for something that simply isn't possible
without going to extreme measures.

Perhaps you can give us a bit more information about your situation.
What kind of noise are you hearing? Do you hear it on neighboring
stations as well? What radio are you using? Can you put the antenna
outside or must it be an indoor antenna? Which station are you trying
to hear and approximately where do you live in relation to the
transmitter? (Or check the antenna pattern at
http://www.radio-locator.com/cgi-bin/home to see if you should be
within the station's reception area.)

Hi Jay; The station I want to get clearly is WQAM Miami, I live in WPB FL, The link You sent shows me just out of local coverage area. I can and do use my box antenna outside, I only have trouble with neighbor station at night. I use a CC radio and Adcom gtp 500. Most of the noise I hear is static. Thank You Alexis.

There is no manual, as such. The directions are printed on a card in
the display pack.

I'll post a scan of the card in Files section. Mine is the Degen 31MS
version, but it is the same as the Kaito.

See my folder Loop Kits in the Photo section. The MTM Scientific AM Loop is approximately 17" x 17" (24" on the diagonal) with 15 turns at 1/8" spacing. The tuning capacitor is a standard 9.6-365 pf tuning cap. There is a 1 turn pickup loop just inside of the 15 turn loop.

http://www.mtmscientific.com/loop.html

http://www.mtmscientific.com/pickup.html

Well, whatdya know? If you click Photos by Customers, that is mine at the top of that page! I didn't know that until just now.

The pickup loop shown is probably better than what I did. You could also make a coax pickup loop, making a, say, 10" dia loop on the end, soldering the center conductor of the very end back to the shield of the coax. I've made pickup loops like that and they work well.

Of course, dimensions may be altered, but that will change the number of turns required, too. I have read comments from those that experimented with sizes that beyond a 2' loop, there are diminishing returns, that is, a 4' loop is not much better than a 2', but I have not built any larger.

So, what is the best loop? I don't know, and I don't think anyone here knows... but there are a number of good designs. And this is THE place to share ideas, see what others are doing, find out what works, what doesn't.

Paul C.

You should be able to hear WQAM on the CCRadio without any trouble at all. You certainly shouldn't need a giant loop. If anything, that's going to overload the CCRadio. I have to think if you're getting a lot of noise in the signal it almost has to be coming from a local source. Have you tried taking a walk with the radio to see what it sounds like outside and at different spots in your neighborhood? Do you get the same or similar noise on other stations? Do you normally use the radio plugged in to AC or on battery? Does it sound different on battery?

If you don't want to walk around with the CCRadio, I recommend getting a Sony SRF-59 for portable use with earphones. It's a great little radio you can get at most Kmarts for $15. Do not let the cheap looks fool you. There's a radio giant lurking under that cheap exterior.

If outside reception is okay, then walk around the house with the radio and see if the noise gets stronger or weaker. I used to have a "green plug" behind my refrigerator that turned out to be a huge source of RFI. I located it using a portable SW radio with the antenna fully retracted. When I got rid of that thing my noise level dropped about 5 s-points.

Really, WQAM should be no problem for you. I'm pretty sure I can get them here in Orlando. It's not a great signal, but it's there.

If you can't locate and eliminate a noise source, I would suggest trying a small, tuned loop similar to the Terk or the Select-A-Tenna. You should be able to inductively couple it to the CCRadio, so just put the loop near the radio and tune the antenna to peak the radio signal on that frequency. You can build your own tuned loop for about $15 in parts. There are plans all over the Internet. (I'd start in the file section for this group.)

Why do you want to listen to the station? Is it technical challenge only or programing you like. You will understand the question as you read below.

What they said, they just may be too week, far and conditions / environment (terrain, RFI far-dist) prevents clean reception.

Hate to say it, have you tried the Internet? Many stations have streaming content.

http://www.radio-locator.com/

Go to link and put the info in and select fringe stations. If it does not show up that is your first clue it is outside their fringe coverage area. If the station does not show, put in the zip code of the town the station is in and try again.

(*** NOTE: THERE IS A LINK TO THE STATIONS COVERAGE MAPS, DAY AND NIGHT. THAT ALONE MIGHT TELL YOU IF THERE IS ANY CHANCE YOU ARE ABLE TO GET THE STATION CLEANLY.)

**** Ignore below if you're JUST trying the Station as a technical challenge ****

When you see the station you will see some info and links to their web page and a icon indicating if they have streaming audio. IF THE STATION has a web page and simultaneous streaming audio of their programing you can go there and listen all day long static free (if you have high speed Net connection).

You can also just google the radios call sign, that might get you direct to the station Net page if they have one. Some times stations don't have live streaming audio but PodCast. Basically the Podcast is audio files of recent programing. You can down load it and play it back on the computer or iPod / MP3 player. I use this a lot for programing.

Is there some particular program you want or need to hear? Is there some synidcaded radio program you want to hear? You can find a station that does carry that program and do the above, go to their streaming audio. The station can be 1000's of miles or half way around the world.

Sadly this is part of the reason SW radio is dying. For example BBC stopped SW radio to North America. Their logic, there're other ways to listen, satellite radio, cable tv and yes streaming audio on the NET. Boooooooo. (but the fact of life, Sat and Net are pretty good for getting live/streaming audio). The down side of both Sat and Net is you need to pay for it. Sat you need a service and special radio and Net you need a fairly expensive high-speed cable internet connection.

Why is that one station so important? If you really have to have it you just might be out of luck.

Topic: 5638 Message: 5638

I'll start with the Cliff Notes first...

Not bad.

First, do look at the instructions and plug everything in with the correct orientation. Don't ask why I say this...

I have it hooked up to my Icom R75 using the Y-cable with clips for ground and ant connection to the R75's Ant 2 terminals. I used some little 2" stubs of wire clipped into the R75's terminals, and attached the Y-cable clips to those.

AM is OK, surprisingly so. The AM reception is not outstanding, but this is a small single turn loop.

Though the instruction card says it tunes from 531-1602 khz, I was able to tune a station at 560 khz, and another at 1700 khz. With both stations there was enough adjustment on each end that I am sure it would go down to 530 khz and up past 1710 khz. It is about 21:00 now and the AM band is still a little crazy.

Tuned up to the 75 meter band. The instruction card says it does 3.9 mhz - 22 mhz in the SW range. I'm listening to some local (in this state and adjacent states) hams on 3.610 mhz and am not tuned all the way to the limit of the tuning wheel.

Plenty to listen to now that the sun is down on 49 meters and 60 meters.

Dialed up to 40 meters, some code, some phone coming in. Some international broadcast coming in just above the ham freq.

20 meters, some code and phone. Didn't find much above 20 m.

All in all, not a bad antenna. And it all fits easily in a Hefty "One Zip" 1 quart ziplock bag.

It has a tiny ferrite bar coupler, about the size of those in "pocket" transistor radios. I pulled out the Grundig S350DL to see how this works. I tried it on AM and SW. Well, not very well.

The Grundig has a very effective ferrite bar antenna, so the Kaito/Degen loop was not much help.

The tuning wheel is not any more difficult to set than a tuning capacitor on a passive tuned loop.

This might be a good choice for the fellow in the nursing home,
though he could do better for an AM antenna.

Paul C.

Hi Alexis,

I've done a bit more research on this and am convinced you should be able to get a decent signal from WQAM unless you have a local noise source interfering.

On my drive home tonight I tuned to 560 and was able to get a weak but listenable signal from here in Orlando. That would have been when they were still on day power of 5kW. Just a bit ago, about 11pm EDT, I tuned in with my Panasonic RF-2200 and was able to get a fair signal from WQAM. There was a Spanish station underneath, but I was able to null them by rotating the antenna. (The RF-2200 has a rotatable ferrite antenna on the top.)

These things lead me to conclude the issue must be one of the following. 1) You have a local noise source that's interfering with your reception. If this is the case, it's unlikely any antenna is going to solve the problem. Your best bet is to find the source of the noise and do whatever you can to eliminate it.

2) You have a MW transmitter nearby that is overloading the CCRadio and causing it to become desensitized. The CCRadio is known for being subject to this in strong signal areas. It's one of the side effects of a sensitive radio that is difficult to overcome. If this is the case, you might have better luck with a less sensitive radio. Or with a radio that has an adjustable RF gain control.

Since you mention you have the same problem with your Adcom tuner, it either shares the CCRadio's penchant for overload, or you have a local noise issue. The latter would seem more likely.

Short of finding and eliminating the noise source, there's not a whole lot you can do. If the noise is coming from a single source, you might be able to use two antennas with a phaser to null out the noise.

Disregard the desired signal for a moment. When tuned to 560, can you rotate the radio to minimize the noise? Don't pay attention to the station, just to the noise. When you rotate the radio does the noise ever get significantly lower in volume? If it does, then the phaser

solution might have some promise.

As to finding the noise, common sources are TVs, dimmer switches, touch-lamps, computers, computer monitors (more CRT than LCD), compact fluorescent lights, regular fluorescent lights. I had a security light that used to generate a huge amount of noise because it was set to stay on at a dimmed level at night, going to full brightness if there was any motion in the area. The noise was horrendous. I changed the settings on the light so it was completely off unless there was motion and the noise went away. I'm sure some of the others can contribute other ideas for noise sources.

I hope this helps.

There was a time when the Dolphins were a team to be reckoned with.

I watched the Bares and the Clots (sic, sic, sic) the other day. Not sure of the Clots will be a contender this year.

Hello,
I live on the Lake Worth/Boynton Beach line and I get WQAM pretty good in the daytime, but I hear what you are saying. No matter which receiver or antenna I use, I still get a Spanish radio station in the background. Maybe look into some mods for your receiver. Check out www.kiwa.com
Hope this helps.
Pat

So what type of results do you get with the 2 foot loop. I have seen these before, so I was just curious.
Thanks,

Are those two stations in the same direction? If not, you could use a phased array of two antennas to cancel out the unwanted one. Modifying the receiver will not help unless the two stations are at different frequencies, and then only if their sidebands do not overlap each other's carriers.

I had not realized just how much manmade noise was present until the power was out a few days due to Hurricane Gustav passing directly over us. Tuning through the AM band with my Grundig S350DL was like listening to FM with mute. With RF gain and volume full up, and placing my ear close to the speaker, I could just barely hear a soft "shhhhhh" between stations, and the occasional soft crackle of distant lightning. Nothing else. I heard distant daytime stations I had never heard before.

This is now moot, as power is back, along with all the other noise. Computers produce a lot of noise, even laptops.

The Spanish station is probably Radio Rebelde in Holguin, Cuba. This is the only Cuban station I can find documented on 560. Holguin is fairly far to the east of your line to WQAM. You should be able to null out the Spanish station by rotating your radio and still get a signal from WQAM. I was able to do so at about 11pm last night. When I tried again later (about 1am) I was getting too many signals, possibly from Mexico in addition to Cuba, and was not able to null them all out.

I don't think any of the Kiwa mods are going to help with this situation. The Kiwa loop might help, but he stopped making those a few years ago.

Hi Jay; I am very great full for Your knowledge and help, I just purchased a Sony SRF-59 on ebay as none of my local stores carried it. I walked around my house with cc radio and I have a noisy house, mostly my home theater hd dvr`s and batt backup. There are some quieter aereas on the street but still pick up static noise. Would a copper tube shielded anntenna help? Thank You, Alexis.

For the most part, if you're in a noisy environment, the radio is going to pick up that noise. Short of getting rid of the noise, a tuned loop is about the best you can do. In that regard, you've certainly come to the right place.

I don't know much about shielded loops so I think I'll let some of the other folks take it from here. Best of luck in hearing the Dolphins.

Interested in SWL, learning about antenna construction. Thus far, all I've built is a 100ft longwire for my Realistic DX-160, and a short indoor 30ft simple wire. I'd like to see what a loop would do. Heard they are pretty directional at lower frequencies.

Excellent! I can tune in a weak distant 860 khz AM next to our local blowtorch WWL 870 AM.

And this loop will tune from 530 to 1710 khz with additional adjustment on each end of the tuning capacitor.

It actually measures 24" on the diagonal, 17" on each side, 15 turns of 22 ga magnet wire at 1/8" spacing, with 9.6-380 pf tuning capacitor.

I couldn't ask for any better for AM. Only drawback is having to tune it, which is not difficult.

I use 4 turn untuned loops with my stereo receivers and tuners. That is the "Ultimate AM Loop Antenna" from a kit sold on eBay by seller jburns1987. This loop measures 12" on each side, 17" on the diagonal, and has 4 turns of stranded insulated hookup wire. The "Ultimate" is much better than the tiny loops that usually come with stereo receivers. At night I easily pick up, from my home on the Gulf Coast, WOAI in San Antonio, WSB in Atlanta, KMOX in St. Louis, WLW Cinncinnati, WLS and WGN in Chicago.

Of course, the MTM tuned loop will bring them in a little better, and bring in other stations the Ultimate won't.

Alex; I've got the 2ft MTM Scientific loop and the CCrane Twin-Ferrite. The 2ft loop will outperform the 1 ft loops currently on the market - ie, Terk. Select-A-Tenna and the two new ones from China. The T-F will work about the same as the 2 ft. loop. Which is better (2 ft loop or T-F)? They are about the same price new. The 2 ft. loop will never need batteries (it is passive) and you don't have to mess around with cables. The T-F is less bulky and you can place the antenna head away from the remote tuning box and your receiver. It's a 50/50 toss up. If however you purchase both, through extensive testing I have found the two antennas working together are an incredible combination. ((i will post audio files on these tests in the next week or so - you will be able to hear what i have learned))

Hope that helps,

Mark

Hi,

not quite .... an antenna is generally considered directional if the
pattern (for reception or radiation as the case may be) is narrow ...
either bi-directional or uni-directional. A Hi-Q loop has a narrow
bi-directional null. As a consequence the radiation pattern is also
bi-directional and rather broad. These small loops are good at nulling out
interference from particular directions while maintaining a rather broad
reception pattern.

The small loop is also more immune (but not immune) to noise than most
other antennas. The other useful characteristic is that since most of
these loops are small they can be located to positions with less noise ....
you would be surprised that moving the loop to a different location a few
feet away can result in meaningful reduction in locally generated interference.

Jim

Go to AES.com and order an Eavesdropper 5 band trap dipole antenna. I have been using one for more than 20 years, it's a very good antenna especially made for SWL.

Jim,
Thanks for the response.
I am very interested in building a loop antenna to try it and compare
to the 100ft longwire I have.

What I meant by my comment, is I thought in the upper frequencies,
maybe about 3-4MHz, the directionality of the antenna for SW
listening (no broadcasting, no license (yet)) would be less than that
at lower-frequencies. Maybe I'm wrong about that, but I'm willing to
learn more and give it a go.

Is there a particular design which would work well enough up through
30MHz which you might recommend or point me to for researching?

I like the characteristics w.r.t. nulling, but also placement and the
reduction in noise. Ideally, this would be something I could place on
my deck at the rear of the house for evening listening /
experimentation.

Putting up and taking down my longwire is a bit cumbersome /
inconvenient. By the time we've finished up dinner, the dishes,
volleyball, baths, stories, bed, I'm toast.
Any help appreciated.
Sam

Your best option will be to use a ferrite rod antenna as the EM field in an environment such as water (fresh or salt) is primarily magnetic and almost no electric field.

Perhaps the best starting point is

http://www.stormwise.com

Which is a source for very large ferrite rods for making low frequency
antennas. You will find a lot of good information there, as well as a
few ready made antennas and a wide range of large ferrite rods.

Hi Sam,

A small (e.g 3' diam approx) tuned loop for frequencies ... 2-10 mhz makes a vy good antenna for the balcony. My downtown apt in the big city on the 9th flr uses such an antenna. I have it fastened to the balcony railing. As I mentioned orientation is for minimum noise and as consequence is a one time rotation ... and the receiving directions are broad. Tuning the antenna to the frequency of interest is the trick. One method is to make the loop from coax and feed it with a standard unbalanced tuner. I deviated from this approach and constructed the loop from ordinary copper tubing and fed it with 300 ohm twin lead and tuned it with a small balanced tuner ... located inside the apt. about 8' from the loop.

I could tune the loop from approx 3 to 11 mhz. The performance is head and shoulders above the built in whip ... or any wire antenna i could jury rig in the apartment.

At my country home ... eg ... small city on lake superior, i use a wire antenna ... certainly not 100' ft long ... more like 40ft. It terminates at a ground connection out in the garden and is then coupled to coax which comes to the house ... buried a few inches under the lawn. The idea is to keep the antenna away from local noise sources which are inevitably located in the house. There is no need for a long antenna like 100 ft. After all we are not using xtal sets ... modern receivers have more than enough gain ... the key is to keep the ratio of signal to noise as low as possible.

That sounds almost exactly like the problem I had with the security light. The house was dead quiet RF-wise during the day. At night there would be a horrible noise almost everywhere. I eventually found the noise was worse in the garage, and finally narrowed it down to one switch. Turns out the security light was wired to an outside socket at the back of the house I assume was intended for Christmas lights. It was controlled by a switch in the garage that was taped into the "on" position and marked "Do not turn off". (I assume a previous owner marked it.) Of course, I turned it off and the noise immediately disappeared.

I eventually figured out it was the dimmer on the security light and it could be configured to stay off until it detected motion. Problem solved.

It was really amazing how the house wiring carried the noise practically everywhere throughout the house.

I'm very glad you were able to find and fix the problem. That was a good approach turning everything off and trying it one circuit at a time. Given how the wiring was propagating the noise, that probably saved you hours of checking things around the house.

I think you meant the key is to maximize the SNR ratio. If the SNR were
low, then the signal would be approxiately equal to or less than the
noise. Not good. ;)

I'll hunt for some designs. Maybe the ARRL wire antenna book will have
something. Any chance you'd post the configuration of the tuning
section you are using in Files or Photos? How about a pic of the
antenna itself? Type / gauge of wire? Spacing of the loops to avoid
self inductance? Values of the variable cap and inductor you're using?

I was hoping a loop could be made that would be workable up through
30MHz; I guess that might be asking too much of a loop - too much
compromise. Again, I have to do some research.
Thanks.

Not that complicated.... 1 loop (3' in dia.) anything at hand .. bigger the gauge the better. No tuning capacitor, up to 12' balanced feed line, 1 balanced tuner (I use a Z-match). The idea is to tune it from a distance ... eg up to 12'. As you change bands/frequencies you tune the loop with the tuner .... very clear noise rush at resonance. Will work to 15 mhz .... in fact even made a few contacts on 20m. The objective was SWL.

>I was hoping a loop could be made that would be workable up through
>30MHz; I guess that might be asking too much of a loop - too much

>Thanks.

I suppose if you adjust the components you could resonant to 30mhz. The most dramatic improvements in reception are in that 5mhz to 10mhz range. I'll check my photos .... I know I have a couple of pics.

My crude 8" loop has worked with WSL Nashville--300+ miles, WWL in New Orleans 280 miles and a station in Dallas. I have two V-caps and the larger 3 gang works the best. Next will be a 2' square with how many loops up to 7 or so I'll need for AM/MF broadcast. I might even use coax and a toroid balun. Will a loop work with shortwave HF? How does it work and how does it connect the best--pick up loop? I have no idea.

The broad reception range and narrow null (fat figure 8 pattern) make
loops ideal for noise reduction.

I use mine placed on an old "Lazy Susan" and rotate it for best
effect. If you are using it with a portable radio, and coupling by
placing the radio near it you will notice the radio needs to be in a
particular orientation with the loop for best effect. In that case,
the radio may be placed on the Lazy Susan and both rotated together.

I have a "pickup loop" added to my MTM Scientific loop and feed my
tuner with a twisted pair, but it works as well with 300 ohm twinlead.

>thanks david

Yes, and no. Yes you can 'stack' 2 small MW tuned loops .... that is bring 2 loops so that they are inductively coupled and interact with one another and in turn are either inductively coupled to the built in ferrite loop in the radio or to a link coil.

No, in that they do not act in the way you are suggesting as in a yagi. Using 2 Hi-Q loops it is possible to separate adjacent interfering signals ... eg tune one for maximum on the desired frequency and the second to minimize the undesired signal. This is a trick used by crystal set aficionados.

This is also a great way to couple a long wire antenna to a radio on MW .... the 2 coupled tuned loops act as an 'antenna tuner' ..... one loop connected to the long wire/ ground and the other connected to the receiver ... makes a dynamite DX combination.

Everything above relates to small tuned loops for MW. Of course you can build a yagi type antenna with full size loop elements (1 wavelength in dia.) for HF and VHF (cubical Quad is the example). However building a full size multi-element yagi type loop antenna for MW would be a major construction program hi hi. Such elements for 600 khz would be about 1700 ft in circumference !!

Hi Jim,

I remember an article or chapter by Joseph Carr (prolific author on loop antennas), there was an illustration of a loop antenna about 24 inches (60cm) apart the receiver and rotated 45 degrees. The receiver used an internal ferrite antenna.

The distance and angle are experimental, but this way Carr related one could control interference.

I really don't know how would this work... Would the rotated, apart antenna be operated at 'anti-resonance' frequency 'absorbing' the offending station?

Hi,

Yes, an external tuned loop can be coupled to the tuned loop in the radio (ferrite antenna) in such a way as to increase OR reduce the amount of signal to the radio. It takes a sensitive 'touch' when adjusting the capacitor on the external loop ... and of course the orientation and distance of the external loop. It is also possible to use 2 external loops in different tuning/orientation combinations to simultaneously increase and decrease signals that are close to each other .... eg. you may have a strong local station at 600 khz that 'splashes' over when you are trying to receive a weak signal on the next channel at 610 khz. It is possible to arrange the tuning so that the signal on 610 is increased while the signal on 600 is decreased. It is easy to imagine how an external Hi-Q circuit can increase the intensity of the electromagnetic field at a certain frequency ... but hard to imagine how it can decrease it in the presence of the receiver antenna. I believe it has to do with adjusting the phase of the intensified field (around the external loop) so that it cancels the field around the receiving antenna (ferrite loop) at a particular frequency.

There are RF interference cancelling devices (MFJ sells a version) that use 2 antenna inputs. The signals from the 2 antennas are mixed and the phase of the signals are adjusted so that any particular signal can be cancelled. The trick that Joe Carr was demonstrating works in a similar fashion.

This is a technique used by crystal set aficionados during receiving contests. All competitive crystal sets use at least 2 Hi-Q circuits ... and many use 3 and 4 since all selectivity of these basic receivers is

achieved at the fundamental frequency of the stations received .... no luxury of a selective IF amplifier hi hi.

Jim

Subject: Re: [K9AYloop] Re: Mini-K9AY

Slightly off-topic, but there is another very interesting small RX
antenna - The W2PM Mini Diamond Receiving Flag

http://www.ok1rr. com/e107_ plugins/content/ content.php? content.76

In contrary to the mini K9AY preliminary study it is proven design which
works. My ~15 dB 2x 2N5109 preamp plus the internal preamp in my Orion
were not the best but it does listen... The main advantage is that this
antenna is ground-independent and can be built as rotatable.

From: aimo ruoho
Topic: 5685 Message: 5685

Sorry, because there was a "_" missing on the address, that I wrote, it gave a zero result...
So, the right email address is the following:
http://www.ok1rr.com/e107_plugins/content/content.php?content.76
I hope,that this came right this time.(Pse look at the original email from Martin@...)
My apologies.

Slightly off-topic, but there is another very interesting small RX
antenna - The W2PM Mini Diamond Receiving Flag

http://www.ok1rr. com/e107_ plugins/content/ content.php? content.76

In contrary to the mini K9AY preliminary study it is proven design which
works. My ~15 dB 2x 2N5109 preamp plus the internal preamp in my Orion
were not the best but it does listen... The main advantage is that this
antenna is ground-independent and can be built as rotatable.

From: Chris Trask
Topic: 5683 Message: 5686

The correct URL is:

http://www.ok1rr.com/e107_plugins/content/content.php?content.76

It's basically a rhombic antenna lying on its side. Launch angle is a
little high.

David,

What you heard was WLAM 1470, an ESPN affiliate in Lewiston, Maine.

If you listen closely at 0:49 - 0:55 , you'll hear "...the next big
story on 870 and 1470, Maine's sports station ..."

Edd- This is my fourth and last reply to you FS posting for this antenna. Other have also respsonded and I've not seen any reply from you! If your AL-1530+ is still available, please rsvp asap indicating what you need for it to be shipped to 01930. I am sincerely interested tho very disappointed in the lack of communication. Thank you in advance.

5696. Edek 26" Inductively Coupled MW Loop and Wellbrook 1530

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-09-17 21:37:47 UTC
From: billmagness
Topic: 5696 Message: 5696

Has anyone had any experience with the Edek 26" MW Loop? I'm considering it for indoor use because of space restrictions. Also, I'm in the market for a Wellbrook 1530 if anyone has one in good shape. I know they make several versions (1530P for indoor use and evidently a 1530+ which is an upgraded version). If anyone has any input into how the 1530 compares to the 5030 I'd be curious to hear that too.

many thanks,
Bill

Hello,

Just joined the group in the hunt for information on loop antennae and
so far found some good info on here.

I'm also trying to find a UK supplier for Amidon T200-2 Toroid cores so
I can wind my own baluns so I can get fully active on HF. Can anyone
point me in the right direction ?

Any help would be appreciated, thanks.

Hi David,
Diz at http://kitsandparts.com/ has the best price and he ships to other countries; maybe consider a non-UK supplier such as that one.

Topic: 5702 Message: 5702

I finally completed the testing and construction of a new form of transmitting loop antenna. This version does not require the usual high-voltage variable capacitor nor the gamma-match or Mini-Loop matching element. The prototype tunes the entire 40M band and is suitable for power levels up to 100W. Return loss is 20dB or better over the band. Power for the motor that adjusts the variable capacitor is sent up the coaxial cable feedline. The preliminary details are available at:

http://www.home.earthlink.net/~christrask/Paper012.html

I will have the usual full details available before long.

5705. Re: [loopantennas] Transmitting Loop Antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-09-20 13:49:17 UTC
From: Chris Trask
Topic: 5703 Message: 5705

The loop element in this one at 15 feet of 1/2" flexible copper tubing. With the connectors, etc., it ends up being just under 1.5m in diameter.

I already had someone ask about a 600M version. The loop would be at least 2m in diameter, made of three turns of 1/4" tubing spaced 1.5" apart. That comes to about 62 feet of tubing.

The three transformers would be a bit of trouble, just as they have been in this HF design due to the very low impedances in the early stages. T1 and T2 would probably be built on Fair-Rite 67-mix toroids (5967001001, available from Amidon), and T3 would remain being built on a 43-mix toroid (5943001001, also available from Amidon).

Hi Cris,
Have you made any QSO's with this antenna? How does it perform
compared to a random wire? Would it be possible to use this with QRP
rigs? Any restrictions on operating height?

Chris
how about a QRO, wide band version of this?
as in 20m thru 90m?? actually, 40m and down would be great.

In other words, a MARS ready antenna which would handle 600W instead
of 600m <G> and be useful in the foreseeable propagation conditions
which we have been suffering thru for the past year?

perhaps a spiral of about 2m diam? not sure what would be needed for
the less than 1kw TX.

I would love to put up something like this at my base. OR use it for
deployment as we have done for three hurricanes in a row now.

thanks
chas k5dam

5708. New Ham question?

Topic: 5708 Message: 5708

Hi

My question is about transmitting loops running on low power shortwaves indoors?

I passed my Canadian (southern Ontario) Basic and Advanced tests (no code) and my license is in the mail on it's way to me.

I plan on building my own equipment (I've already started prototyping my ideas). I want to work shortwaves on relatively low power (under 30 watts), AM phone.

Has anyone experimented with low power transmitting loops indoors? Which frequencies should I make the loop for?

Thanks,
geo

Geo,
I don't know much about indoor antennas for AM low power, but some guidelines for AM operation (at least in the U.S.) can be found here (including the W1AW AM operation schedule):

http://www.arrl.org/tis/info/am.html

AM Phone enthusiasts seem to hang out here.

http://amfone.net

Try posting a message in their AM Forum.

HTH,

5710. Capacitor Designs

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-09-20 21:35:09 UTC
From: Neil McGrath
Topic: 5710 Message: 5710

The most expensive component required for a home-brew loop antenna appears to be the tuning capacitor. Does anyone have any good designs for the construction of a home brew cap using simple tools.

Neil

Hi Neil
Have a look at "Antenna Jottings" by G3JKF

on the Crawley Cclub site at

http://www.carc.org.uk/pdf/Archive_015.pdf

he uses copper clad board as the capacitor plates and an electric screwdriver to move one of them.

I'm also interested in any other ideas !

Regards

Steve, g4vbd

Hi Neil and Steve,
I think one of the best articles on building a transmitting loop capacitor
was
published in the November 1994 issue of QST magazine. The title is :
A Homebrew Loop Tuning Capacitor - by Bill Jones KD7S.

Bill describes building a trombone-style capacitor out of copper pipe,
elbow fittings, Teflon sheet for insulation, a threaded rod and motor tuning.

I built one similar to it for a 10 meter transmitting loop and it works
flawlessly. Very smooth tuning and not a trace of heating or arcing
at the 100 watt power level. It is much easier to build than trying to
use flat plates or circuit board material.

Also keep in mind the phenolic or epoxy grade circuit board material
is a lossy dielectric and not recommended to be used as a high voltage
RF capacitor. Teflon insulation is the best.

73 Todd WD4NGG

Steve is right about the use of the trombone capacitor. For motorized tuners used over a relatively narrow frequency range, the trombone can be a very inexpensive alternative to buying a commercial variable capacitor. I may try one of these in my motor-driven loop tuner later on so as to further reduce the costs.

Could someone scan that Jones article and add it to the files section?

not a good design of the caps is the square sheet
you get fringing dielectric field and no wonder he gets rf in the screwdriver windings

again a trombone affair might be better as dielectric field contained between the concentric tubes

wondering if someone supplies teflon tubing as low friction for movement and would stand high voltage

some kind of trombone design here might be best

maybe there are other ways of building tunable capacitors besides the expensive vacuum capacitors

some of these are available on ebay from the former soviet bloc

best
Paul

I'm taking a break, myself. I have two active antenna projects pending,
plus a direct-readout VSWR meter. Spent a bit of $$ these past four months
on parts and electricity for the test equipment. The local ACE hardware
store has gotten used to me once again going in and playing with all sorts
of parts.

Plus, this is the beginning of gardening season.

Hi David and All

I'm glad to be of help.
Les is a good seller to deal with , I've not had any problems with anything
I've bought from him.

Did anyone else see the review of the G4TPHJ Mag-Loop antenna in Radcom this
month?
That looks like a possible interesting use for a T200-2, and I'll be trying
one using a 1 metre aluminium circular loop.

There's nothing new there, other than perhaps the "flat pack" construction
method, and I'm not too sure I'd be totally happy with a review of my product
that gave so much information it almost begged to be copied, but it looks
like it could be be fun to play with.

regards

Nigel

You wouldn't be able to tune it as easily as the real part of the
impedance would change too much. THat's why I included that chart of real
impedance (Fig. 1). You would end up with a real impedance that varies from
20 ohms to over 500 ohms at the tuner input.

Chris,

Very nicely done and easy to follow.

Thanks,

Eric

5725. Clear up a doubt about multiband antennas?

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-09-22 15:58:04 UTC
From: Jose Emilio
Topic: 5725 Message: 5725

My name is Jose Emilio Martinez, de Valencia, Spain.

I enjoy hours listening HF signals as CW, SSB and TTY trying to
decode digital modes

I have an antenna discono Diamond D-130, designed for VHF, that I use
for HF listening but with poor results

And this is my doubt

What results will give for listening of utility frequencies bands
betweeen 5 to 10 MHz?), an vertical or horizontal multiband antenna
designed with coil tramps for all HF amateurs bands? or for this ones
announced for all HF broadcasting bands?

I should be grateful if somebody experienced can answer me

Best regards

Kenwood R2000+VHF module, Icom R175
Diamond D-130

Hi,
My son has gone off to the hardware shop nop with a pur5chase list to try and build this antenna. Will report back when completed.
Many Thanks
Ron

Seems that quite a few people have become interested in this antenna. I may add to that document to show how to improve the efficiency by using a 2.5m diamter loop and a 1:1 current balun for T3. Not that much of a change, really, since the loop element can be swapped out by way of the PL-259 connectors.

PL-259 connectors.

****

Dear Chris
I think you have give a lot of thought to this problem.
In particular, I really like the way the PL-259 connectors have been used to solder on the ends of the copper tubes. This provides and easy and very good electrical connection using the male connectors to the female on the pvc post

very well done

5730. Re: [loopantennas] Clear up a doubt about multiband antennas?

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-09-23 18:56:15 UTC
From: Andy
Topic: 5725 Message: 5730

> I have an antenna discono Diamond D-130, designed for VHF, that I use
> for HF listening but with poor results

Yes, most discone antennas are made for VHF and up, and do not work well on HF frequencies.

> What results will give for listening of utility frequencies bands
> betweeen 5 to 10 MHz?), an vertical or horizontal multiband antenna
> designed with coil tramps for all HF amateurs bands? or for this ones
> announced for all HF broadcasting bands?

I am not sure ...

But I think the multiband antennas with traps are optimized for only the amateur bands, and might not work that well on the utility frequencies which are between the amateur bands. Also, the trap antennas are specifically designed to minimize the SWR (on the amateur frequencies), which is mainly important for transmitting, not something you need.

I would think about using a simple random wire antenna. Or perhaps a loop, which might be more resistant to noise, though most loops tend to be tuned so they might not work well over a wider frequency range.

An antenna that is advertised for all HF broadcasting bands might be a good choice. But you could probably make one yourself for less money.

Regards,
Andy

5731. Re: [loopantennas] Clear up a doubt about multiband antennas?

Yahoo group: loopantennas (2008 — 2012)

From: aimo ruoho
Topic: 5725 Message: 5731

I would like to suggest an all-band-antenna like DX-1 Professional MK II (mark 2), made in Holland. Universal Radio is still selling it in the USA for $ 699.95.

One other possibility would be the British Wellbrook ALA 100 M for $355.
I suggest it to be used with a rotor to be able to rotate a Loop 360 degrees any time needed.
This is an wide-band antenna amplifier, which wants to have help of a rather small self-made loop to give you most of the reception, you are after...

I have both of them and as now they are the best of the lot of about 40 or so antennas, that I have in my very possession. Most of them are home-brewed and some commercial.

If you have or want to buy the famous PASSPORT TO WORLD BAND RADIO-
book via AMAZON or elsewhere, you will know a lot more about offerings of antennas and add-ons and receivers and radio stations and their frequencies and sending times...

If you are interested, I will try to find and send you addresses of the sellers and other needed information...It is not too difficult to build a good 10 kHz to 50 MHz antenna at home. And it may be a lot better and cheaper, than most offerings around!

Best luck!
Amigo

I have read opinions that using Heliax for a transmitting loop may not be
as efficient as using plain copper tubing. The outer copper shield in Heliax
is
corrugated copper and may have higher RF resistance compared to smooth
copper pipe. Also the plastic covering may lower Q especially with the high
voltage RF potential developed across the loop.

Those potential problems may not affect performance that much but did want
to pass along what I have read. If you have some Heliax to play with it
wouldn't hurt to give it a try. It shouldn't make any difference if you
connect the
inner conductor to the outer shield or leave it floating as all the RF
current is on the
outside of the shield.

Howdy group.
I have some new Air Variable Capacitors for sale. They are new still in plastic wrap. Here is the link with the photos and specs:
http://illumiview.com/Air%20Variable.htm
I used two to make a Pi network tuner and they mount well with the casting they have. I used a pair of turns counters on the shafts.

christrask@... writes:

Do you ever have anything of any value to post on these groups, or are
you simply trying to establish yourself as a widely-recognized moron?

Interesting that you should respond in such fashion to what was actually
quite a harmless remark, we are a bit sensitive where Mr Birke's concerned
aren't we?
Interesting too that whilst I never quite judged Paul Birke as a moron I did
realise some while ago that he does have a rather worrying personality, and
that you do yourself no favours by association.

When Paul first appeared on this group he was asking questions that
indicated he had little prior knowledge of radio and/or antennas in general, and I
went out of my way to help him and to answer his questions.
However, after a while I was intrigued, and eventually annoyed, when I
realised that he was using a technique of turning around the answers he received,
not just mine, as further questions, in a way that sought to imply
understanding but in fact landed a heavier burden on those trying to help him.
He may have thought nothing of this but, to someone taking time out of an
extremely busy schedule to help him, it felt very much like what we call here
"taking the piss".

His behaviour at that time was extremely reminiscent of some of the crude
artificial intelligence software from the 70s and one such program, LISA,
particularly comes to mind.
This software was claimed to be able to hold an "intelligent" conversation
but did so by using a very similar technique whereby, for example, answering
"it's cloudy" to the question "what's the weather like where you are?" would
draw a response something like "do you like clouds" etc etc.
This is a rather simplistic example but suffice it to say that 25 years
experience of security surveillance and monitoring never threw up a "real" person
who behaved in quite that same way, it is indeed most peculiar.

I've still to decide whether he's very clever, and by that I do NOT mean
intelligent, or just mentally unstable but, either way, such things are no
longer my problem.
Unfortunately, his mental state does seem to have deteriorated since he's
adopted his rather sycophantic attachment to you, and, again, you don't really
do yourself any favours by encouraging it.
That, coupled with your derogatory and condescending attitude to any who've
attempted to duplicate some of your technical claims but have found the
measurements don't hold up, has considerably reduced any respect I might have had
for you and the information in your so called "papers", which is a shame

really as there are a few interesting ideas in there.

So there you have it.
If you wish to consider me a moron please feel free but, with a certified IQ well above the 99th percentile, I'm happy to assume your judgement there is as much at fault as it is in your choice of pets.

I'm still not sure if you bit on my comment through your usual arrogance or just through an ignorance of things British but, in case it's the latter, perhaps I should explain that the "Royal" "we" has become a bit of a joke over here.
For some obscure reason it's customary for the British monarch to use "We" when meaning "I" and the question "is that the Royal we?" has come to be a light hearted response to anyone suggesting that "we" were doing or thought something or other, etc etc, when what they really should have said was "I".
In this instance, when Mr Birke suggested, somewhat patronisingly, that "we" had been discussing receiving antennas only, it didn't seem unreasonable to suggest that may have only been his opinion, or of course yours as they're the same thing anyway.

Hmmmmmmmm.....
I really don't know why I'm even bothering to answer you, what on earth have YOU ever done anyway to deserve MY time??

However, since I have blessed you with a response I will of course include the group in my reply, as well as Mr Birke, since even those so severely challenged as he still deserve to be considered normal until there really is no hope.

It is, of course, an interesting consideration that, in groups such as this, the relatively unskilled and uneducated can generate a "name" for themselves by quoting a few formulae and churning out some "papers" that, in the real world, would be subjected to a much more intense and well informed scrutiny.

Go walk your dog, Sweetie.

regards

Dr Nigel Clarke

Despite what you perceive to be faults, he is at least civil, which is
far more than we can say for you, especially after your last outrage
resulted in the lockdown of one of the other antenna-related lists.

And it's very unfortunate that you have chosen to take an off-list
remark and turn it into a public display of your own peculiar shortcomings,
pouring your outrage on yet another audience that really doesn't deserve
such absolute nonsense.

Chris

christrask@... writes:

Despite what you perceive to be faults, he is at least civil, which is
far more than we can say for you, especially after your last outrage
resulted in the lockdown of one of the other antenna-related lists.

I wish you both a long and happy life together, he certainly sounds much
more wonderful than I ever imagined, but I don't think I ever achieved quite the
fame you claimed.
I hate to call you a liar deary, that would be ever so naughty, but perhaps
you could explain further about the "lockdown", as I certainly think you
might just be telling porkies.....tsk tsk...or should that be......trask trask is
perhaps a bare faced liar after all?

And it's very unfortunate that you have chosen to take an off-list
remark and turn it into a public display of your own peculiar shortcomings,
pouring your outrage on yet another audience that really doesn't deserve
such absolute nonsense.

An off list "remark"?

Come on turd brain, even someone as mentally challenged as you must be can't
possibly deny that you offered that "remark" as a supposedly "superior
person" comment, but were short changed when it was shown to be load of mindless
crap that demonstrated the sickness in your soul.
I have no outrage, I smile benignly:-).....but I do worry about you.
Tell me dear, have you been taking your tablets?

You know what the doctor said about you getting stressed, and that's why I
worry about you and that Paul, he may be a sweetie but are you really sure
he's the one to have your babies?

I do so wish we could stick to those wireless loop thingies and forget all
about these smutty sidelines, whatever would that nice Mr Marconi have thought,
that's what I'd like to know?

PLEEEEEEEEASE do take your medication

Lots of love

Mummy

God, I'm certainly glad to hear that. He had done the same thing
earlier on the 2N5160 antenna group, which resulted in it being locked down.
He's obviously very, very disturbed and shouldn't have access to any of
these groups at all.

I reported him to Yahoo! abuse and encouraged a few others to do so as
well. He needs to be gotten rid of permanently.

Yes thanks Steve

my question relates to the fact that receiving and transmitting
antennae are or can be quite different animals

what is good for receiving may not be reciprocated for transmitting

my interest remains with the original question raised re the use of
Heliax in a transmitting loop configuration and to what power levels
with what size of Heliax (without the black covering but maybe some
other covering not affected by rf em field and heat)

best
Paul

Forward the email with an introductory complaint paragraph to abuse@.... Normally I would put such people into the spam filter, but in this case I'm letting him continue with his venting and later I'll forward them one at a time. The more the better, as one or two complaints has little impact, if any at all.

5756. single turn loop v multi turn loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-09-29 08:35:09 UTC
From: DAVID
Topic: 5756 Message: 5756

i have been doing a few tests on a single turn mw loop against a 6 turn mw loop and i have found the single turn loop is MUCH quieter than the multi turn loop and is rejecting the european splatter off the back of the loop with ease. the single loop is the same dimensions as the pick up loop in the multi turn loop ie 7 feet long and 5.9 feet high its fed at the corner i want for maximum direction with a 48/11 turn ol balun and in the oppostie corner i have a 1000 ohm terminating resistor i did try a viariable resistor here but couldnt get a dip. i also use the palstar aa30 active antenna / pre selector on the single loop. the results have surprised me as i didnt think there would be much of a difference but there is a big difference. both loops are in my attic and i think the 6 turn loop will be made into a single turn and pointed to africa. you can hear the difference here

5757. Timewave ANC-4 or MFJ-1026 phaser with loop antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-09-29 14:59:25 UTC
From: al_ka5jgv
Topic: 5757 Message: 5757

I am seriously considering purchase of a phasing unit such as the Timewave ANC-4 or the MFJ-1026. My main application for the unit is in the 200 to 550kHz range and my main purpose is to eliminate 60/120Hz noise. My main antenna is a 4-1/2 foot diameter multi-turn tuned loop. I would like to continue to use this as my main and I'm open to opinions on what to use for the second antenna.

I have done a pretty good scan on the Internet and found quite a few articles including the one by Mark Connelly on modifying the MFJ-1026 for LF coverage. I therefore somewhat favor the MFJ over the Timewave because of this.

I would really like to hear views on the usefullness of one of these units for eliminating line-type noise in the frequency range mentioned.

I have posted this message to various groups in order to get a broader coverage. I hope this is acceptable and not in violation of group policies. I apologize if it is.

Thank you.

Unless all your noise is coming from one specific source, I don't think a phaser is going to really help you. They allow you to combine the inputs from two antennas to create a single null region and steer it electrically. They're great for reducing interference, be it a nuisance local station or a source of QRM, but only if that interference is coming from just one point source. If you're getting 60Hz noise from the electrical system in your house or your neighbors house, a phaser is not going to help because the noise is coming from all around.

Looks great, Chris. I studied the paper, and have one question.

Figure 1. shows the radiation resistance vs. frequency of a 1.5 M
loop, which are the measured, not calculated, values.

My question is, how is the radiation resistance so high? The highest I
have ever seen as a predicted value is much lower than that, even for
methods that claim traditional values are too small.

To what do you attribute this high radiation resistance? I would like
to build one of these, but would like to believe it works as it is
supposed to.

Thanks.

Tony,
That chart is total resistance (radiation plus loss). In a 2-part series I wrote for QEX back in 2003, I had a similar chart for a 1m diameter loop made with 0.25" tubing. There, you can see that the resistance is going from a first-order (linear) to second-order (nonlinear) curve as it approaches the first parallel resonance. The analytical approaches used in that article show this as well.

I'm going to make a bending form so that I can make loops from 1/2" rigid copper pipe and see if there's a difference in the resistance. I'm curious as to whether the other metals in the flexible tubing alloy (zinc?) are significantly raising the loss resistance. I couldn't find anything online about this.

Nor could I find anything about a homebrewed pipe bender. It was suggested some time ago to use a large spring that plumbers use in bending PVC pipe, but those are not long enough for bending a 10-foot piece of copper pipe into a 1m radius arc. Guess I'll make a heavy form out of plywood and fill the pipe with sand.

5764. Re: Transmitting Loop Antenna

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-10-01 20:18:14 UTC
From: dldorrance
Topic: 5703 Message: 5764

Hi Chris,

Like Tony, I would like to see some way of estimating total total resistance, in order to know what size loop for what band(s) will transform with what total step up value of transmission line transformer(s).

Regarding bending copper pipe. Are you talking about standard copper pipe, or are you talking about soft copper tubing, which comes in 1/2 diameters in most hardware stores and should be easy to fashion into a circle?

Dave WA6YSO

I've already published measured resistances for 1/4" and 1/2" copper
tubing for a couple of different diameter loops. You can estimate the
resistance for other sizes and bands by scaling them.

>

That would be 1/2" rigid copper pipe for later on. I'm already using
the flexible tubing in 1/4" and 1/2" diameters.

5767. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-10-01 23:26:42 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 5767

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Although it will allow arbitrarily large images, it will only show them to the moderator and whoever uploaded them. Everyone else can only see a resampled max of 300x400 pixels. So anything over that in Photos is a waste of storage. So crop in to the important parts and resample to about 300x400. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. If you need to post a schematic diagram that would be unreadable at 300x400, I strongly suggest the Files section as it has no such limitations.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Amplifiers for Antennas and Pre-Selectors
http://members.cts.com/king/j/jlkolb/site/ant.htm
- presented by John Kolb [KK6IL]

Four(4) Schmatic Diagrams are provided:

* The KRS AA-1 Active Antenna was sold through Radio West
in the early '70's, and was a good performer.
http://members.cts.com/king/j/jlkolb/site/aa-1.pdf

* In the '70's, this Circuit was developed suitable for
use as an Antenna Pre-Amplifier or as the Amplifier for
a Box Loop Antenna or Ferrite Rod Antenna.
http://members.cts.com/king/j/jlkolb/site/fet_pre.pdf

* A fancier version, with a Dual-Gate FET, featuring an
RF Gain Control. Dual-Gate FET's can still be found,
but not easily. This Schematic is closely related to
a Pre-Selector sold as the KS Pre-Selector.
http://members.cts.com/king/j/jlkolb/site/dual_fet.pdf

* Better Nulling is obtained with a Loop Antenna when it
is Center Tapped and Amplified with a Balanced Amplifier.
http://members.cts.com/king/j/jlkolb/site/dif_fet.pdf

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Justice AM Loop Antenna (Active)
- - - http://www.ccrane.com/justice_antenna.asp

* Torus Tuner 27" Loop Antenna (Passive)
- - - http://www.torustuner.com/

* Select-A-Tenna Model #541M (Passive)
- - - http://www.selectatenna.com/

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.
http://ecforster.netfirms.com/LpAnt/Doc1.html

Very Low Frequency (VLF) Up-Converter
STORMWISE: Palomar VLF Converter allows you to use your ordinary ShortWave Radio to listen below the AM Broadcast Band. Directly Tune VLF Stations of 10 KHz to 500 KHz using your existing ShortWave Radio. The VLF Converter easily connects between the Antenna and the Radio.

.
Hi Al,

First I am not sure you actually mean 60/120HZ noise. For the most part such 'noise' that appears in your speaker or earphones is usually not radiated, but is propagated by the power system ... in which case the antenna phasing unit would be of minimal value. Not to be a stick in the mud, the phasing unit is most useful on particular frequencies and not generally noise that appears across the band. For example ... the fish tank heater or electric blanket next door may have a control unit that radiates loud RFI across most of the spectrum. Phasing will give little help. However, if you have two signals on the same frequency coming from 2 different sources it is possible to adjust the phasing such that one of the two signals will be greatly reduced in strength.

In my experience a phasing unit is of minimal use for general line 'noise'.

Now as far as the receiving antenna ... If you are dealing with a locally generated signal then almost anything will do ... a local whip would be sufficient. However if you are trying to separate out 2 MW signals on the same frequency ... or adjacent frequencies ... then the 'second' antenna must produce sufficient signal in order to cancel out 'phase out' the signal received on the primary antenna.

I have no experience with the particular units you mention ... (I have also thought of getting the MFJ unit) .... but I have used the technique in other venues and I must say i am always amazed how it is possible to make one signal disappear leaving the other one (next to it) intact.

5775. Just made my first transmitting loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-10-03 08:24:41 UTC
From: Dave Andrus - K7DAA
Topic: 5775 Message: 5775

Folks:

Even though I've been a member for a bit, I haven't tried my hand at making my own transmitting loop until now.

I just completed my first one, and wanted to share my info and ask a question or three. Sorry in advance for the long posting. I hope that someone might find it interesting! ;-)

I made a single-turn loop using 5/8" copper pipe from a roll I bought at Home Depot. It helped that the roll was already formed into a coil that was about 18 inches in diameter, so it was a simple matter to uncoil the roll into a larger loop without any serious distortion or kinks.

I had previously bought a very nice Hammarlund dual-gang capacitor from eBay that works very nicely for this purpose. Since the two 8-220pF sections are electrically separated, I don't have to make a connection to the rotor, so this is the ideal capacitor. I wish I had a few more of them. Anyway, in this split configuration, I've got an effective capacitance range of about 4 to 110pF.

I mounted the loop with tie wraps on a piece of wood that's .75 by 1.5 inches. The capacitor is also securely mounted to the wood with tie wraps, and soldered to the top of the loop with very short pieces of 10 gauge solid copper wire that I hammered flat--just to make it easier to shape and bend them. So from a distance, the overall design looks like a big lollipop, so to speak.

For the feed, I used the conventional RG-58 loop 1/5 (actually a bit closer to 1/6--about 6 inches dia.) the diameter of the main loop. The center conductor is soldered to the shield at the half-way point, with the shields soldered together at the bottom. This smaller loop is then tie-wrapped securely to the bottom of the main loop, with no electrical or metallic bond between them.

Oh, and I forgot to mention that the main loop diameter is 39 inches. It is one continuous circle with no breaks or solder points other than where the tuning capacitor attaches at the top. This was just a convenient size for me to shoot for--1 meter in diameter.

I've checked the expected 2:1 SWR bandwidth at 10.1 and 14.2 MHz, and those numbers agree very closely with the predicted values that the loop design software suggests, so this tells me that I've got decent loop "Q". Good.

So, I'm VERY pleased with its functionality so far. I know this might sound like a cliche, but my very first two QSO's I tried yesterday late afternoon on 17 meters netted me some great DX! Both stations that I called heard me on my first call. I was using an Elecraft K2 transceiver running on its internal battery, using about 10 watts on SSB. The wooden boom for the loop was pushed into soft, wet grass, so the bottom of the loop was about 12 inches above the grass.

I'm near San Jose, California, and I first called a station in Hawaii at the end of a QSO, and got a 5-7 report. He was running about 400 watts, and I also gave him a 5-7! Ten minutes later, I called a station in Maryland, and got a 5-5. He was running 900 watts, and I gave him a 5-8. Both stations were very surprised that they could hear me as well as they could, considering my low power and small antenna. (By the way, the late-afternoon QSB on 17 meters yesterday was tremendously long and deep--almost like 10 meters during a sporadic E opening.)

So...I have a couple of observations, mostly about the feed system, and I wonder if those of you with way more experience than me could comment and offer suggestions and improvements.

With the first feed loop (described above), I was not very pleased with the SWR I could get, even after fooling around with the loop shape and amount of coupling with the main loop. I did not attempt to increase or decrease the diameter of this loop, and I know it was a bit smaller than the suggested 20% of the outer loop's circumference. Had I fiddled with this for awhile, I'm assuming that I could have gotten the SWR down. Best I could get was about 1.6 or 1.7 to one. Not horrible, but everyone else seems to report something approaching unity.

Instead of doing that, though, I decided to try the "other" type of feed I've seen suggested, so I changed it to the type where you ground the coax shield to the bottom of the main loop with a stainless hose clamp, then solder the coax center conductor to about 14 inches of 10 gauge wire that follows the inner curvature of the main loop, but about 2 inches to the inside of it--out to about 10 inches, where another pipe clamp shorts it to the main loop. This is just like the feed that W2BRI shows on the "build it yourself" square loop article on his web site. I experimented with the length and proximity of this feed, and was easily able to get my SWR down to 1.1:1 pretty much anywhere from about 10.1 to 21.45 MHz.

What I didn't realize until today is that this nice, low SWR is not going to be realized continuously from the lowest to the highest frequency that the loop can cover without changing the length of this new feed system. For instance, I'm only able to get about 2:1 SWR at 28.1 MHz unless I shorten the coupling loop wire length, but then my SWR at the loop's lowest frequency increases to about 1.7:1 at best. Am I doing something wrong here, or is this to be

expected? Am I just looking for a compromise value, or should
I really expect something close to unity SWR from top to bottom?

Also, is the first feed system I tried better than what I'm using now
for broader-band use, or are they pretty much the same expected
performance? Why use one over the other, then?

The reason I'm asking about this is that if I end up putting a motor on
the tuning capacitor for remote, continuous tuning, I can so far only
get good SWR for the lower half of the loop's frequency range, or for
the upper half, but not for the complete range that my tuning cap
will cover. I'd obviously like to be able to get a nice, low SWR across
the entire frequency range that the loop can cover.

Last question: I note that on one or two ham websites, there is a
warning that the tuning or shape of the coupling loop will change
when you move the loop around. One even suggested that you
really haven't "tuned" your loop until you get it into final position,
and only then can you make your final adjustments. Great, but that's
kinda difficult to do when you have it hoisted out of reach. My limited
observations so far seem to suggest that the actual frequency that the
outer loop is tuned to changes a bit, of course, but the SWR seems to
change much more noticeably than the tuning when going from 12"
above ground to 12 feet.

For instance, I get 1.2:1 SWR mounted near ground level at 14.060 MHz,
but then when I move the loop so that it is supported by a fiberglas
ladder at a height of about 8 feet, the SWR goes up to maybe 1.9:1,
but the resonant frequency only shifts down (at least in my case) by
maybe 20 or 30 kHz or so. I can live with the frequency shift, and it's
simple to retouch the tuning cap, but to change the SWR, I've got to fiddle
with the coupling loop length or position--not nearly as easy to do.

Any suggestions are very welcome, and thanks in advance for your
kind thoughts or encouragement. I'm getting a real kick out of this,
especially because my local CC&R's will never allow me to put up
even a simple dipole. I expect to park my loop in my small attic
eventually, and am looking forward to having a semi-decent stealth
antenna!

73,

Dave--K7DAA

The wooden boom for the loop was pushed into soft, wet grass,
so the bottom of the loop was about 12 inches above the grass.

****

Dear Dave
from what I have read in the literature magnetic loops seem to work well closer to ground than farther away--so what you have is good as indicated by the excellent contacts you have reported

yet I am wondering if 12" is too close
However I have a photo of a German Military loop and it seems to be near yours being between 14" and 20" of the ground ground from what I can scale from the picture

it also has a more elliptical shape with the long axis parallel the ground

I am wondering if perhaps 12" is "too close" and is affecting the SWR minimun and by increasing the spacing somewhat you might be able to get a better minimun
and also and perhaps more importantly to SWR,I have a paper from Switzerland showing the optimal shape for a transmitting loop is more like a rectangle with well rounded corners hence the nice shape of the German loop which is like a flattened loop
it could be easy for you to raise the height of the loop to say 24" and maybe also to force flatten the circular loop you have and see if SWR minimum is affected

best
Paul

If I disconnect the antenna and the noise goes away, can I confidently say that the noise is propogated rather than conducted? That is the situation in my case. I now suspect that the noise is coming from a nearby power pole light. I will time it's turn on and off time and see if there is a relationship. Is there a sure way of testing a noisy power pole, other than shooting the light out? I believe the city does not like that.

> Not to be a stick in the mud, the phasing unit is most useful on
> particular frequencies and not> generally noise that appears across
> the band.

Unfortunately that is what most of the replys have said and unfortunately my noise is across the whole LF band and into MW AM.

> However, if you have two signals on the same frequency coming from
> 2 different sources it is possible to adjust the phasing such that
> one of the two signals will be greatly reduced in strength.

There are times I like to chase AM signals and I do find multiple signals on one frequency. It will be interesting to see how the 1026 does in these situations. I use a 4-1/2 foot loop for direction control and it helps a lot. If the 1026 adds to this then things will be better. If I could just get rid of that noise.

Thanks Jim.

Al -

The Timewave is a DSP noise remover as opposed to the MFJ phaser. Are you using an R-75 (I think)? If so does that units DSP noise reduction have any effect at all on your noise?

Bob

Hi Dave,

Sounds like you have your new loop working pretty well using the Gamma match type feed. That seems to work best for me also. It is to be expected the SWR will change when trying to use the loop over so broad a frequency range with one set length for the Gamma match.

I would recommend building two loops - one for the high range 15-10 meters and build a larger one for the lower range 30-20 meters. A larger loop will give you better efficiency on the lower bands also. If you use only one loop to cover that wide a range it will have to be a compromise setting for lowest SWR.

Best to adjust the SWR of the loop at least 6 feet off the ground. If you can get it 8 feet off the ground adjust it there. The SWR should hold pretty close from there if you hoist it up higher. Or if you put it in an attic then set the SWR there.

I would recommend looking into building a better tuning cap also like the trombone-style cap made out of short lengths of copper pipe and using Teflon insulation between the pipes. A regular 'bread-slicer' variable cap is not considered efficient enough for a transmitting loop unless the plates are welded together but many people seem to report good results using them. You wouldn't notice any problems using them at low power but the loss might still be there. Any bolt-on or screw-on connections to a capacitor should be avoided. A trombone cap is soldered directly onto the ends of the loop so it is very low loss.

Also beware of any connecting wires between the loop and the capacitor. Just a few short inches of #10 wire has more RF resistance than the entire loop conductor. Using flexible braid is reported as being very lossy also. If you have to make any connections between the loop and a capacitor use only flat copper strip at least 1 inch wide like copper flashing.

Band conditions are so variable that it might be hard to notice if a loop was really running at top efficiency or not depending on skip. Best way to really tell is if you have someone local within 10-30 miles that can hear you on groundwave. Then any changes will show up on his S-meter that you can rely on.

Paul - a couple questions. Why should a loop work closer to ground if it's basically a ground-independent antenna? I would think more height = better. Also, i think to maximize inductance a round coil is best, so why would the rounded rectangle in the Swiss study be preferable? Just briefly, how do they explain the reason for its advantage? Thanks- Hue Miller / K7HUE Newport, Oregon

5782. Re: Just made my first transmitting loop

Todd (and Paul):

Thanks for your thoughts!

I just bought some 2-inch wide copper flashing from HRO, and I'm going to try using a narrowed strip of it on the tuning cap connections instead of what I have now. You make a very good point about the losses in even a short piece of 10 ga. wire. I hadn't thought seriously about that, but it makes sense.

I'm also going to try adjusting the loop in a fixed position about 6 feet high and see what results I get. I'm also planning on running steel wool around the copper pipe to clean off any oxidation and then spray it with urethane or something similar.

I'll share my results here when I get the time to experiment more. I actually took a day off
from work just to build the loop! Now I've got to find more time to tweak and poke at the basic design. I'm very encouraged by what I've seen so far, though.

I'd like to try a 40 meter loop next, maybe an octagonal shape using straight pieces of 1 inch diameter copper pipe that's maybe 1.5 to 2 meters in diameter.

It's very instructive to feed these various dimensions in to the loop design software and see what the results are--also very gratifying to find out that I can build something that comes pretty close to the predicted values!

Thanks and 73,

Dave K7DAA

5783. The RF Noise Identification Website

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-10-04 23:09:54 UTC
From: Jeff
Topic: 5783 Message: 5783

This link has been very helpful to me in the past:

http://www.arrl.org/tis/info/HTML/rfi-noise/

There are audio clips of different types of noise.

Jeff - NE0DX

> Paul

Paul - a couple questions. Why should a loop work closer to ground if it's
basically a ground-independent antenna?

the use via pictures I have observed are close to the ground
If you look at the information on the internet it seems it performs well enough in this position

I would think more height = better.

one would think so

Also, i think to maximize inductance a round coil is best, so why would the
rounded rectangle in the Swiss study be preferable?

well they went overboard a bit, rereading I notice the constraint was a rectangular shape so it remains a question is circle better than rectangle shape for gain-what they were looking at optimizing

they used calculus of variation to find the optimal and this was with large rounded edges but the gain advantage was only 0.12 dB

Just briefly, how do
they explain the reason for its advantage? Thanks- Hue Miller / K7HUE
Newport, Oregon

Again it is an interesting question as to whether a more rectangular shape of elliptical is somehow better than a circle

I will try to find out more about this

The German photo I have show an industrial antenna (not necessarily military as I first suggested)
however it is definitely a flattend circle and mounted on a multi pod about 20" from the ground

There are loops for the us military and they are rectangular in shape, maybe because of the vehicle but nontheless
rectangular with rounded corner just like the Swiss solution

others may know more the reasons why

[1] some advantage to gain or directivity
[2] swr
[3] bandwidth
[4] other

best
Paul

Street lights, refrigerator motors, neon signs, fluorescent lights,
and a multitude of other things can make wide band noise. I used to
hear horrific noise from some motor or another at a machine shop 1/4
mile away back in my Novice days. Fortunately it was intermittent,
else 80 meters would have been unusable. Maybe some sort of "high
pass" filter would help on the antenna feed.

.....
.....

Hi Hue, to your first question, maybe the magnetic field is stronger near ground.

I think in a transmiter using a vertical antenna and ground, the electical field lines going far from the antenna and returning by the ground as hf currents. In that case, near ground means more coupling to the loop (that is really a coil)

My two cents?
Jose

5787. Heliax Loop

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-10-05 10:17:54 UTC
From: Neil McGrath
Topic: 5787 Message: 5787

I have just completed my first magnetic loop and the initial results look promising. It is a circular 4 ft diameter design made from heliax ,Farady loop fed and tuned using a 120pf air spaced capacitor. The design tuned well on 14Mhz showing an SWR close to 1:1 inside my garage with plenty of metal in close proximity. The variable cap still had too much capacitance on its minimum setting to operate the antenna on 21MHz and on 7Mhz I could hear the background noise start to rise but ran out of adjustment before I could get a decent SWR. I am thinking about making a capacitor to be connected across the variable for operation on 40m and have considered using a piece of double sided PCB cut to a suitable size. Is there a better option using off the shelf components?

Neil

Hello Bob,
Yes I'm using the R75 receiver and it does have DSP noise reduction (NR). When you turn on the NR things do get quieter, but if you listen carefully, the signal also get quieter. If you look at the signals using Spectran, the drop in the signal is the same as the noise so the net reduction in signal-to-noise ratio is near nothing.

I did get an MFJ-1026 modified for the LF range. I'm in the process of figuring out how it works and can it be used that low in frequency. If not, it still should be helpfull for general SWLing.

From: DAVID
Topic: 5789 Message: 5789

hi and sorry if you are getting bored with the antenna updates but i spend more time tweaking/making antennas than i actually do listening.

the story so far the 7 by 6 feet multi turn loops are now down i have 2 single turn loops 1 nw and 1 w and yes even at that the difference is amazing.

both are fed with a 48/11 turn overlaping baluns and each has a 1000 ohm resistor in the opposite corner.

i cant get over the back rejection on these antennas i put a switch on the nw loop at the resistor so its inline and off and i sent my freind some clips of what it can do ie slovenia on 918 khz when the resistor is open its a s9 but put the resistor in use so the main lobe is nw its either not there or very weak in the noise and i think my friend is going to make one as well and join the group.

the next thing i am going to do is setup a series of switching so i can have all the directions just like a k9ay loop not to bad for antennas in the attic.

PHASING WITHOUT A PHASING UNIT

IF I PUT A SMALL 1X1 MULTI TURN LOOP WITH A TUNING CAP IN SIDE MY FLAG/LOOP AT THE FEED POINT OR RESISTOR I CAN EASILY NULL OUT STRONG LOCALS IE RADIO SCOTLAND

ON 810 KHz AND GET EUROPEAN SIGNALS. I MUST POINT OUT THAT THE RESISTOR IS IN THE OPEN POSITION IE NOT IN USE THIS SAVES ME BORROWING MY FRENDS MFJ ALL THE TIME LOL

David,
So, are you getting better signal strength with the single turn loop?
Or just better rejection? How about coverage? Do they tune the same
range as before? Are you switching the resistor out manually or is
there a remote of some sort?

From: david/lorraine
Topic: 5789 Message: 5791

hi i would say the single loop is down on signal to the multi turn loop BUT much more quiet and the single loop can hear things the multi loop cant to the direction the single loops are beaming due to no splatter.

i cant get over how the single loop with one resistor rejects the europeans so well. the single loop can cover the whole mw band which is all i am interested in i havent checked above. i am manually switching the resistor in and out as they are in my attic with my radios its not a problem. so in summary the single loop while slightly down on signal for me anyway is a better dx antenna as it can hear things that the multi loop cant due to splatter/noise etc .... thanks david h

Al -

Well, the dsp should be better, but that built in one is not so great
as some of the externals..

By the way, I confused the Timewave units - I guess when I think
Timewave, I immediately think of dsp, but you were talking about their
antenna phaser... sorry for any confusion.

5793. Question from loopy beginner

Yahoo group: loopantennas (2008 — 2012)
Date: 2008-10-06 18:10:05 UTC
From: John
Topic: 5793 Message: 5793

Hello,
I've been lurking on the group for a few months & have a few questions.

I've been reading the literature on antennas and picked up the
following facts, which are slightly contradictory:

1) In general, a doublet (dipole) is resonant on odd harmonics, but
can be multi-band if fed by twin feeder from an ATU.

2) Folded dipoles tend to be resonant on only the fundamental
frequency & make poor multi-band antennas.

3) Full wave loops are resonant on even harmonics, and make good
multi-band antennas when fed from an ATU. They also appear less
affected by low heights than dipoles.

Is not a full wave loop merely a folded dipole stretched out, in which
case why do they behave so differently?

I have a 160 metre dipole for which I've just got an SGC auto tuner.
It works OK, but I can only manage a height of 10 metres which is a
tiny fraction of a wavelength. I've thought of joining the ends
together to make an 80 metre loop, or even of adding another 80 metres
wire to make a top band loop - I've got plenty of flat space, but not
many supports!

Any recommendations? Like David, I live in Scotland, in Lanarkshire.

Thanks,

John

****
one thing is that there is magnetic coupling between the currents in the foldeded loop

ie the mutual inductance between top and bottom is not zero

best
Paul

Hi,

Yes, for example a 64' dipole is a resonant 1/2 wave on 40m, a resonant 1 wave on 20m and 2 resonant full waves on 10m. It is not a resonant length on 15m . However, if you feed the 64' dipole with 50 ohm coax it will only represent a workable load on 40m. The fact it is resonant on 20 and 10 m as well is simply an academic fact. However, if you feed the 64' dipole ... or in fact just about any length as long as it is at least close to 1/2 wave length on the lowest frequency of operation ... with open wire line and an appropriate tuner ... it can be workable and efficient on all bands .... (due to the low loss of the balanced feed line in the face of high SWR).

>2) Folded dipoles tend to be resonant on only the fundamental
>frequency & make poor multi-band antennas.

Interesting ... I have used a number of folded dipoles in the past and always for a single band ... I never really tried multi-band operation ... or gave it any thought ... I would be interested in results others may have experienced. A folded dipole fed with a 4:1 BALUN makes a great antenna which will handle high power with high efficiency ... albeit on a single band.

>3) Full wave loops are resonant on even harmonics, and make good
>multi-band antennas when fed from an ATU. They also appear less
>affected by low heights than dipoles.

I have less experience here .... and defer to those with more experience ..... again, what experience I have would indicate that as with a doublet/dipole .... resonance is not necessary for effective all band operation .... as long as the loop is close to a full wavelength at the lowest frequency .... again ... fed with open wire line and tuner.

>Is not a full wave loop merely a folded dipole stretched out, in which
>case why do they behave so differently?

Definitely not ..... the close proximity of the wires in the folded dipole causes the antenna currents to flow 'AS ONE'. In a loop the antenna

current at points opposite to each other flow in opposite directions .... the folded dipole the flow in the same direction .... as if they were 1 wire. Breaking into only 1 wire at the feed point causes the antenna to function as a transmission line transformer, (4:1), transforming the feed point impedance from 50 ohm to 200 ohm (approx).

>I have a 160 metre dipole for which I've just got an SGC auto tuner.

Again I defer to those with more experience. Most of my experience is with vertically oriented loops.

> can be multi-band if fed by twin feeder from an ATU.

Right. The dipole is resonant with half a wave stored along
its length (a pair of quarter wave elements, fed from one
end, with a total propagation delay out and back, of a half
wave, with the polarity reversal at the reflection off the
free end providing another 180 degrees, making up 360
degrees or zero degrees for the wave out to the end and
back). So at 3 times that frequency, it holds about 3/2
wavelength (3/4 in each half for 6/4 propagation delay and
the reflection providing a half cycle phase shift for a
total out and back phase shift of 4/4 or back in phase with
the next wave from the feed line). Though its feed point
impedance and radiation pattern changes at this and higher
order resonances, in general, any odd number of half
wavelengths that fit on the element will produce a resonance.

> 2) Folded dipoles tend to be resonant on only the fundamental
> frequency & make poor multi-band antennas.

I don't think so. The two close coupled parallel elements
resonate essentially as a single element. Their currents
are essentially in phase with each other. (If their
currents traveled in opposite directions, they would not
radiate.)

The main difference with respect to a single line dipole is
the feed point impedance, since only a bit more than half of
the total standing wave current (passing through both
dipoles) passes through the feed line. Same voltage with
less current equals a higher feed point impedance. But the
standing wave resonance frequencies remain very similar to a
single element dipole, since the two dipoles share pretty

much the same space and fields.

> 3) Full wave loops are resonant on even harmonics, and make good
> multi-band antennas when fed from an ATU.

I'm not so sure about that.

> They also appear less
> affected by low heights than dipoles.

They have a completely different radiation pattern, since
they are not at all a one dimensional linear dipole, but a
two dimensional radiating object.

> Is not a full wave loop merely a folded dipole stretched out, in which
> case why do they behave so differently?

The resonance is simply based on the wave propagation around
a length of conductor (in both directions, simultaneously),
with no polarity reversing reflection at a free end, as with
the dipole. There is no strong coupling across the middle
of the loop as there is with the transmission line like
structure of the folded dipole.

> I have a 160 metre dipole for which I've just got an SGC auto tuner.

I think the optimum orientation for a circular loop is not
parallel to the ground, but perpendicular to it. So I don't
think it helps with your low height limitations.

Thanks Jim,

your explanation of the folded dipole versus a loop makes sense - I'd never really thought of it like that, nor seen a clear explanation.

Yes and no.

A dipole is resonant at all even and odd harmonics. The problem is, if the dipole is centerfed, for the even harmonics, the feedline joins where there is a "node".

Picture a guitar string vibrating at fundamental frequency. It is vibrating in the middle, but is stationary at each end where it is attached.

If you were to lightly touch the string in the very middle, the tone would suddenly jump up one octave, to double the frequency. If you were to look at that string vibrating with a strobe (I have done this), it is now vibrating at 2x fundamental, and there is a node in the middle, where the string is not vibrating, and antinodes (max vibration at the 25% and 75% points.

If you were to lightly touch the string, vibrating at fundamental frequency, 1/3 of the way along, the tone would jump up (in musical terms) an octave + 5th, the string now vibrating in three sections, with nodes on each end, where joined to the guitar, one node at 33.33% along the string, another node at 66.66%.

And antinodes between those nodes.

If the feedline is right in the middle, at 50%, of your dipole antenna, it is picking up directly on the antinode, where there is maximum energy at the fundamental. On the 3rd harmonic (3 x fundamental) there is again an antinode at the 50% point. Ditto with all other odd harmonics.

And there are nodes at the 50% point for all even harmonics.

So, it is not that the antenna is not resonant for even numbered harmonics. It most certainly IS resonant for even numbered

harmonics. The problem is that a center feedpoint is not located to pick up the even numbered harmonics.

This is why an "offset center fed" dipole is used when it is desirable to pick up the even harmonics. An offset point is choses that is a compromise, that will fall closer to the antinodes, and farther from the nodes, for the even harmonics.

You might find these helpful:

http://www.w8ji.com/windom_off_center_fed.htm

and

http://www.radioelectronicschool.net/files/downloads/ocfdipole.pdf

The second paper especially has diagrams that show the distribution of nodes and antinodes vs. feedpoint.

That particular antenna is part of a system and was used with the receiver section of the AN/TSC-99 Special Forces Burst Communications Base Station.

The antenna was made by Heremes in Canada and is now made by United States Antenna Products.

This URL will provide you with information on their Aperiodic Loop Antenna Arrays: <http://www.usantennaproducts.com/pdf/hermesloop.pdf>

Hi,

Excellent explanation of resonance, harmonics, and node locations on wire antennas. Now, when feeding a wire with open wire line, the antenna itself does not have to be resonant to radiate effectively. A balanced open wire feed line .... in conjunction with a tuner/coupler provides the overall resonance. However the feed line portion does not radiate (if properly installed) since the electromagnetic fields cancel out as they are close and parallel to each other.

Many thanks to all of you for the very clear explanations of how a dipole resonates.

Since you've told me that a folded dipole is close coupled, with the currents in phase, then can I assume that the usual air gap is unnecessary? If a tuned length of substantial twin flex was fed at the centre of one conductor via a 4:1 balun, would it work just as well?

All this doesn't really help me with a decision about the most suitable antenna to use, but I'm tempted by the ARRL "Sky Loop" fed by an SGC 239 auto tuner since I can locate this some distance from the house & tune it remotely. I have a field beyond my garden, and as long as I don't disturb the sheep I can do what I like, as long as it is not permanent. ie, unlimited open space but nothing to hang things on. I've got an old Tennamast welded onto a trailer chassis (stabilised with guy ropes) which is one support - I'll try to get hold of another similar structure & support a horizontal (or sloping) delta loop.

The other option is a long wire or V beam, but I don't actually want a fixed directional antenna.

Thanks again,

John

They also look similar to the loops used in the antenna array produced by C&S Antennas Systems of Rochester in the UK.
I've put a picture of one of these loops in the Photo files.
I later converted this anenna this loop by changing the head unit to a Wellbrook one.

Jim,
An antenna cut to resonate at 7Mhz (40 meters) will also resonate on 21 Mhz (15 meters) I've worked a lot of DX across the pond on a 40 meter dipole strung about 20 feet high between two houses.
The thing is this: a half wave is around 72 ohms at the center at resonance, one and a half waves are also around 72 ohms impedance; hence the 40 meter dipole works well on 15 meters.

Everything you said is correct, open wire feeders and a tuner will load up on just about any band. Each installation is unique, so you may run into some odd behavior on some frequencies, where theory says it should work, it may not.

An 80 meter dipole fed with open wire line (called a center fed Zepp) and hooked to a balanced tuner will also work on 40, 20, 15, and 10. If you short the feed together and tune it like a random wire, it should work on 160. A 160 meter dipole fed with open wire line should work well up to around 20 meters or so. It may act funky on 15 and 10, try it and see. If the feeders are resonant at some multiple of the base frequency, that could cause problems on the higher bands. You can also feed it from one end (an end fed Zepp) and it should work as well.

A good ground is necessary for any of this to work well. Keep the feeders outside the shack, keep the tuner as close to the feed point as possible (window or wall). Of course the above is relevant to a transmitting antenna more so than receiving, but the antenna efficiency will give you better results in receiving as well.

Pappy Hiram

The fact it is resonant on 20 and 10 m as well is simply an academic fact. However, if you feed the 64' dipole ... or in fact just about any length as long as it is at least close to 1/2
wave length on the lowest frequency of operation ... with open wire line and an appropriate tuner ... it can be workable and efficient on all bands .... (due to the low loss of the balanced feed line in the face of high SWR).....

Tracey,

There was a short article in the May 1970 Wireless World relating to a Canadian EMI loop array. The description and pictures look very similar to the Hermes system?

10 years ago I did try to emulate this array using 8 x ALA1530s strung out with a 4m loop spacing along a 28m transmission line of RG62. Unfortunately the velocity factor of the transmission line restricted the usable F/B to approx. 22MHz. However, there was a useable F/B of between 10-20dB from 6-22MHz. If I had the time I would re-engineered system and probably use delaylines and combiners to improve the performance.

Years ago (many) .... I had a 100' inverted vee strung from a 30' mast on the peak of the roof of a 2 story house. It was fed with 300 ohm twin lead. My shack was in the basement .... I did as you said, shorted the feed line and used it as a vertical with a 100' top hat on 160m. I used to join a round table of prairie farmers who got on every morning (before milking). I used a 100w AM transmitter (everyone was on AM). That was a great 160m antenna ... with the iron pipes of the heating system as the ground hi hi.

I also used a 100ft dipole on 20m as a double zepp hung up in the trees at about 60'. It was also a great antenna.

You might want to look at this form of a multi-band longwire antenna:

http://www.radioelectronicschool.net/files/downloads/ocfdipole.pdf

It's an off-centre fed dipole. There's a very unique 6:1 balun
described in this which can only be realized with a pair of current baluns,
not the Guanella balun as described in the paper. I've seen too many
instances of people using the Guanella 4:1 transformer as a balun, and you
simply cannot do that. You can, however, use it to make a 16:1 voltage
balun.

Yes, basically. Made in the same factory on the same lines.
Tao Qu on Ebay apparently has a deal with the factory to put his
TG34 label on it, and claims to ask the factory to do further quality
checks on his TG34 antennas before he receives them to sell on Ebay.
I bought one from him and then ordered a second.
Not as good in reception as the Sony folding loop, but then the
Sony costs three times as much as the TG34 and is a much larger package.

In my opinion, considering size and cost, the TG34 is a damn good
deal.
For the price of the Sony loop, I could get three TG34's and they
fold up into a smaller package for backpacking and travel then the
Sony does as well.
Well worth the price.

Neil.

I have used a piece of coax as a capacitor in the past. It is simple beyond belief and works quite well. You did not mention if you wanted to be able to transmit but if you use rg-213 or similar it will handle the output of your rig or always has for me anyway. The nice thing about a short piece of coax is that one can easily trim it to resonate where you want just by snipping the length till it comes in. Of course, with the variable capacitor you have a wider latitude for the length of the "gimmic" capacitor.

If you want the loop for receive only then the same thing can be done by just twisting a couple of wires together to make a quick and dirty capacitor.

I have been using maganetic loop antennas for the past 3-4 years, mostly for receiving but I also build mine to transmit on, however it was not until just yesterday that I finally managed to complete a most satisfactory method of remote tuning from within my shack. Now with the simple turn of a knob I can tune my main loop to cover any one of 3 of the ham bands. 40, 30 and 20 meters. The loop is located 20 meters from my radio room.

QRZ my call and there is a link to my web page with some photos albeit not quite up to date.

Neil.

I have used a piece of coax as a capacitor in the past. It is simple
beyond belief and works quite well. You did not mention if you
wanted to be able to transmit but if you use rg-213 or similar it
will handle the output of your rig or always has for me anyway. The
nice thing about a short piece of coax is that one can easily trim it
to resonate where you want just by snipping the length till it comes
in. Of course, with the variable capacitor you have a wider latitude
for the length of the "gimmic" capacitor.

If you want the loop for receive only then the same thing can be done
by just twisting a couple of wires together to make a quick and dirty
capacitor.

I have been using maganetic loop antennas for the past 3-4 years,
mostly for receiving but I also build mine to transmit on, however it
was not until just yesterday that I finally managed to complete a
most satisfactory method of remote tuning from within my shack. Now
with the simple turn of a knob I can tune my main loop to cover any
one of 3 of the ham bands. 40, 30 and 20 meters. The loop is located
20 meters from my radio room.

QRZ my call and there is a link to my web page with some photos
albeit not quite up to date.

5821. Verdigris effect on loop Q

Yahoo group: loopantennas (2008 — 2012)

Has anyone seen any quantitative studies done on the impact of the buildup of verdigris on the Q of a copper loop?

I'm working on creating an experiment but won't spend the time on it if there is already published info.

Someone did do a study on the effect of corrosion on the Q of small
copper coils. He found very little change in Q but I don't know how that
would translate to a large single-turn copper loop. His report is here:

http://www.bnk.com/W0QE/inductor_Q_tests.html

It would be common sense to clean the corrosion off of copper used
for a transmitting loop. Most people recommend cleaning the
copper to a shine then coating it with a clear overcoat like
polyurethane.

Now that's a thorough study of the effects of corrosion on copper and
how it effects inductor Q. The link to the G3YNH site offers an even more
detailed discussion about inductors and skin effect, etc.

Hi Paul.

I can pass on my method. First things first. I am using a homebuilt air-variable capacitor that seems easily able to handle the 100 watt output from my radio. Over time I have learned that making a remote tuning device to work it is not so simple as one might think. The first thing I found out was that anything in the plane of the loop wanted to effect the SWR so I had to devise a method of circumventing that.

I finally settled on using a servo motor such as I use in my model airplanes. The requirement for one is not particularly stringent as the capacitor is very low friction (Butterfly type of capacitor) so any cheap servo motor seems to do the job. The servo motor is fixed directly to the capacitor shaft and the three wire cable to provide the signal is routed through the 3/4" pipe that forms the loop. Doing this takes it out of the plane of the loop and has no apparent effect on performance of the loop.

The following numbers are "item numbers" from Ebay auctions:
320309451655, 290266317566

Go to Ebay.ca or Ebay.com and enter the numbers in the search window and the specific listing will be brought up. (note: these numbers will only be good for a couple of months then they will expire from the Ebay system, -- An alternative would be to search for Servo Tester on Ebay)

These devices are servo testers that RC enthusiasts can use to adjust the servo motor settings on model cars/aircraft without having to connect them to a receiver. The less expensive one is rather simple (and small) but works just fine. The more elaborate one has a digital readout that displays the pulse width being generated and can be used as the loop tuning device with complete accuracy. Repeatability is excellent with this device.

I did find that I had to use a stable regulated power source in the shack as a DC wall wart did not work when under load as the circuit

became unstable and the servo motor chattered considerably. What I used (quickest for me) was a battery pack consisting of 6 NIMH rechargables. I have 75 feet of cable from the shack to the loop. Other than the fact that the tuning is very touchy, it works beautifully and I learned very quickly which numbers on the readout correspond with my most used frequencies.
